A method is reported for the determination of cadmium in electroplating wastewater. An aliquot of the cadmium sample (less than 5 micrograms of cadmium) was pipetted into a 60-ml separating funnel, adding 2 ml of 0.2% 1, 10-phenanthroline, and 7 ml of 2N sodium hydroxide, and diluted nearly to 28 ml with distilled water to give approximately a 0.5 N basicity in sodium hydroxide. Then add 0.5 ml of 0.025% ethanolic solution of Cadion and exactly 5 ml of chloroform and shake vigorously for 2 minutes. Allow the phases to separate and then drain off the chloroform layer into a dry small test tube, and measure the absorbance in a 1-cm cell at 490 nm against reagent blank. (Baker-FRC)

PROBLEMS OF THE DETECTION OF ORGANIC TRACE SUBSTANCES IN WATER (ZU PROBLEMEN DES NACHWEISES ORGANISCHER SPURENSTOFFE IM WASSER),
R. Koch.
Acta Hydrochimica et Hydrobiologica, Vol 8, No 1, p 3-17, 1980. 1 Fig, 6 Tab, 73 Ref. (No English Summary).

Descriptors: *Chemical analysis, *Water quality, *Organic compounds, Gas chromatography, Thin layer chromatography, Sample preparation, Data acquistion, Experimental design, Screening, *Toxins, Trace levels.

The possible methods for detection of individual toxicologically relevant water contaminants are reviewed. Prerequisites for performance of analytical screening are outlined. Methods of test substance enrichment, separation of mixtures, and detection and identification of individual compounds are discussed, along with questions of the systematization and standardization of test methods and data acquisition. The importance of the sampling procedure employed should not be underestimated. The principal enrichment techniques performed today are adsorption and liquid/liquid extraction. Gas chromatography (GLC) and thin-layer chromatography (TIC) are the most common methods for separation and identification of individual substances. Results obtained by TLC are often confirmed by IR, UV or fluorescence spectrometry, and GLC results by mass spectrometry. A great variety of solvent systems are available for TLC separation of various groups of substances, and group regents serve for detection of specific substance groups. Screening of water samples for unknown contaminants, followed by specific confirmatory techniques, is now possible. Analysis of all compounds present is not necessary for water quality or public health purposes; a selection must be made based on the toxicologic significance, ecological fate, productin quantities, and application areas of the compounds. DETERMINATION OF ARSENIC AND ANTIMONY IN WATER AND SOIL BY HYDRIDE GENERATION AND ATOMIC ABSORPTION SPECTROSCOPY,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands).
J. A. Haring, W. Van Delft, and C. M. Bom.
Fresenius' Zeitschrift fuer Analytische Chemie, Vol 310, No 3/4, p 217-223, 1982. 6 Fig, 6 Tab, 9 Ref.

Descriptors: *Metals, *Water analysis, Atomic absorption spectroscopy, *Arsenic, *Antimony, Water quality, Soils, *Pollutant identification, Colorimetry.

This report describes the optimization of analytical parameters such as temperature of the quartz cell, pH of the sample and the effect of the valence of the elements in the sample on the rate of metal-hydride formation, as related to the determination of arsenic and antimony in water and soil. Descriptions are also offered of the graphite furnace technique and a colorimetric method. During the intercomparison experiments, the importance of adding potassium iodide before the addition of sodium borohydride reagent to the sample was clearly demonstrated. Compared with the colorimetric technique, the atomic absorption hydride technique with the heated quartz cell was found to suffer from interferences by other hydride forming elements. Slow addition of NaBH4 (over 5 minutes in case of the colorimetric method) resulted in a longer reaction time, giving a complete transformation of the hydride forming elements. The optimization of various analytical parameters with respect to the hydride technique is discussed. (Baker-FRC)

FINGERPRINTING INORGANIC ARSENIC AND ORGANOARSENIC COMPOUNDS IN THE SITU OIL SHALE RETORT AND PROCESS WATERS USING A LIQUID CHROMATOGRAPH COUPLED WITH AN ATOMIC ABSORPTION SPECTROMETER AS A DETECTOR,
California Univ., Berkeley. Lawrence Berkeley Lab.
R. H. Fish, F. E. Brinckman, and K. L. Jewett.
Environmental Science and Technology, Vol 16, No 3, p 174-179, March, 1982. 3 Fig, 3 Tab, 31 Ref.

Descriptors: *Oil shale, *Arsenic, *Industrial wastes, Chemical analysis, Public health, Environmental effects, Hazardous wastes, Toxicity, Path of pollutants, *Toxins, *Pollutant identification.

Inorganic arsenic and organoarsenic compounds were speciated in seven oil shale retort and process waters, including samples from simulated, true, and modified in situ processes, by using a high performance liquid chromatograph automatically coupled to a graphite furnace atomic absorption detector. Molecular forms of arsenic were identified in these waters for the first time at ppm levels and shown to include arsenate, methylarsonic acid, and phenylarsonic acid. The significant environmental finding is that these potentially toxic inorganic arsenic and organo-arsenic compounds in varied mixtures at appreciable concentrations are either released or synthesized during oil shale retorting processes representing present day technology. The possibility of their bioaccumulation in soils, water and edible biota at appreciable distances from the retorting site via disposal of retort leachate waters containing bioactive forms may represent potential health hazards for humans as well as a threat to aquatic species. BIOLOGICAL MONITORING OF HAZARDOUS WASTES IN AQUATIC SYSTEMS,
Environmental Monitoring Systems Lab. Las Vegas, NV.
V. W. Lambou, and L. R. Williams.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 11-18.

Descriptors: *Bioassay, *Monitoring, *Aquatic environment, Aquatic life, Water pollution, Pollutants, Environmental effects, Bioaccumulation, *Hazardous materials, Population density, Species composition, Wastes, Biological samples.

Biological monitoring has had a relatively weak supportive role in monitoring programs of the past; however, it is rapidly attaining the recognition it warrants in a systems approach to monitoring. Physical and chemical testing cannot predict the cumulative impacts and/or the interactions of mixed pollution sources on environmental health. Biological monitoring is well-suited for this as the biota in aquatic systems responds to the sum of the interactions of environmental factors and integrates their effects over time. Approaches to biomonitoring include in-situ bioassays, bioaccumulation, use of indicator organisms, community and population changes, and species health. For selection of appropriate biomonitoring techniques, the monitoring requirements of a specific program should be clearly determined; the selection criteria provided should be reviewed and prioritized relative to those monitoring requirements identified; and the selection criteria should be rigorously applied in determining those tests or measurements needed to meet program objectives. Biological monitoring methods which are sensitive, simple to apply, reproducible, and economical in their application, and which provide answers to vital environmental questions in realistic time frames, are already in use and will have increasing application in the future. NEW IN-SITU TECHNIQUES IN BIOMONITORING,
BioControl Co., Inc., Port Sanilac, MI.
H. E. Schlichting, Jr.
In: 2nd Interagency Workshop on In-Situ Water Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 55-58, 1 Tab, 7 Ref.

Descriptors: *Biomonitoring, *Bioindicators, *Water quality, *Aquatic life, Chemical properties, Physical properties, Water pollution, Algal growth, Biomass, Species diversity, Morphology, Prediction.

Continuous in-situ biological monitoring systems continually assess the responses of selected indicator organisms to the changes occurring in the water chemistry and physical parameters. Successful prediction of water quality changes depends upon the selection of indicator organisms, membrane filter selectivity, and the measurement of pertinent physical and chemical data at the test sites. Measurements of biomass increase, organism health, species diversity, and morphological and physiological changes can be used to estimate the degree of eutrophication or the presence of toxic pollutants. Algal growth potential when determined for a period of a year, can be used in predicting future water quality changes. The importance of recording the physical and chemical parameters, including light, is noted. Biomonitors can be used in other studies including measurement of radionuclide bioconcentration, degree of toxicity of sewage effluent, heavy metals, pesticides, growth regulators and fertilizers in selected organisms in strip mine ponds, lakes, and rivers. It is necessary to couple biological with chemical and physical data for effective environmental protection and quality control. Continuous biological monitoring is not routine because of the cost and time required for examination of the biological material. Progress in automation of biological mon-

LIBRARY U. OF I., URBANA-CHAMPAIGN

itoring has led to an early warning system, automated identification, automation of behavior analysis, and simulation of variable effluent discharges. The automated early warning system monitors fish movement and breathing during continual exposure to a diluted waste stream. A distress response is used to trigger an alert so that remedial action can be taken. The automated identification unit is a pattern recognition system using species such as diatoms. Sample counts are made, and on the basis of species diversity and numbers an evaluation of pollution level may be made. Automated behavior analysis has been used to obtain preliminary estimates of preference, avoidance, and induction of aberrant behavior in fish exposed to pollutants. A unit has been designed to monitor fish ventilation in response to variable effluent discharges such as are likely to occur in streams. More work is required before it can be used as a routine monitor. Automated monitoring can be cost effective and provides improved data analysis, storage and retrieval capabilities. (Brambley-SRC)

ENZYMES AND ANTIBODIES AS SENSORS OF TOXIC SUBSTANCES,
Midwest Research Inst., Kansas City, MO.
D. R. Sellers.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 143-160, 6 Fig, 2 Tab.

Descriptors: *Enzymes, *Water pollution, *Pesticides, *Biodetection, *Antibodies, Electronic equipment, Monitoring, Bioindicators, Air pollution, Effluents, Industrial wastewater, Soil contamination, Phenols, Metals, Phthalates, *Toxins.

Biodetection is the name given to the use of a combination of electronics and material from living tissue for the estimation of compounds in nature. The biological part, either an enzyme or an antibody, provides rapid sensitivity and specificity while the electronics portion magnifies the signal into readout formats. Most work has been done using cholinesterase, in part because it is sensitive to organophosphate and carbamate pesticides. The enzyme can be immobilized for detection of pesticides in water or impregnated in a base for detecting pesticide vapors. Both applications are in commercial use, monitoring wastewater effluent from a pesticide plant, and monitoring the air within the plant, respectively. A soil analysis technique has also been developed. Fifty-two enzymes have been identified which are inhibited by one or more compound on the EPA's priority pollutant list in the groups pesticides, phenols, metals, and phthalates, so that there are good prospects of incorporating them in biodetection equipment for continuous monitoring. An antibody-based biodetection system has been developed to detect 2,4-dinitrophenol. It uses a coupled enzyme system to amplify the signal and provide a display related to the amount of antigen present. (Brambley-SRC)

BIOPROBES FOR THE MONITORING OF TOXIC COMPOUNDS AND HAZARDOUS MATERIALS IN WATER,
New Orleans Univ., LA. Dept. of Chemistry.
S. S. Kuan, and G. G. Guilbault.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 161-165, 12 Ref.

Descriptors: *Monitoring, *Bioindicators, *Enzymes, *Water pollution, *Hazardous materials, Electronic equipment, Nitrate, Nitrite, Cyanide, Carbamate pesticides, Electrodes, Decontamination.

Bioprobes and analytical systems for fast, simple accurate, selective, and sensitive assay have been developed for a number of compounds, including the water pollutants nitrate and nitrite, cyanide, and carbamate pesticides. The nitrate/nitrite bioprobe depends on the successive reduction of nitrate to nitrite by nitrate reductase, and nitrite to ammonia by nitrite reductase, and the measurement of ammonia by an ammonium ion selective electrode. The ammonium ion electrodes used include nonactin membrane electrodes, air gap electrodes, or gas selective membrane electrodes. The systems may use either soluble or immobilized enzymes. Biological detection and decontamination systems have been developed for cyanide using the enzymes rhodanese and beta-cyanoalanine synthase, and cyanide and sulfide electrodes. Both soluble and immobilized enzymes have been used in either batch or flow systems. An aryl acylamidase enzyme extracted from Pseudomonas striata has been found to be able to hydrolyze phenyl or methyl carbamate pesticides, with methylamine detection by an air gap electrode. UTILITY OF THE MICROTOX LUMINESCENT BACTERIAL ASSAY FOR THE RAPID ASSESSMENT OF AQUATIC POLLUTION,
Beckman Instruments, Inc., Carlsbad, CA.
A. A. Bulich.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 173-184, 4 Fig, 2 Tab, 11 Ref.

Descriptors: *Bioassay, *Bacterial physiology, *Luminescence, *Water pollution, *Testing procedures, Toxicity, Pollutants, Effluents, Monitoring, Metals, Phenols, Alcohols, Pesticides, Aromatic compounds.

The Microtox Toxicity Analyzer is a bioassay system using luminescent bacteria which has potential as a rapid, reliable, and inexpensive method for assessing the toxicity of water samples. The system is used to determine the concentration of chemical which produces a 50% reduction in light emission for 5 min (EC50). EC50's were obtained for 20 substances, including metals, phenols, alchols, pesticides, and aromatic hydrocarbons, and these figures were compared with 24-96 h fish toxicity bioassays. A good correlation was observed between fish toxicity and luminescence reduction. Similar correlations were observed when complex effluents were used rather than pure compounds. An improved testing procedure allows a determination of EC50 to be completed in 30 min. The Microtox system appears to be a convenient reliable approach for the rapid determination of acute toxicity of water samples. (Brambley-SRC)

THE USE OF ALGAE AS BIOLOGICAL ACCUMULATORS FOR MONITORING AQUATIC POLLUTANTS,
Academy of Natural Sciences of Philadelphia, PA. Div. of Limnology and Ecology.
S. L. Friant, and J. W. Sherman.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 185-206, 8 Fig, 3 Tab, 52 Ref.

Descriptors: *Algae, *Bioaccumulation, *Monitoring, *Water pollution, *Bioindicators, Metals, Water chemistry, Organic compounds, Water pollution source, Nonpoint pollution sources, Diatoms.

An overview is presented of possible biomonitoring uses of algae as aquatic pollutant bioaccumulators. While metals and other pollutants found in animal tissues may originate in the water column, this is the only source of the substances for algae. The uptake of metals by algae is, however, affected by pH, ligands, competition of metals, and the natural background matrix. These influences must be investigated before algae can be used for long-term monitoring. Algae (primarily diatoms) colonizing artificial substrates have been analyzed for metal uptake over long periods, in some cases up to 20 years. The colonizing period has been two weeks, after which the algae are removed from the slide and subjected to extraction procedures followed by chromatographic analysis. This method has been used to survey rivers for trace metals and trace organics. The results show that the method may be used to assess point source discharges of biologically available pollutants, and the effects of dilution and to identify chemical sinks in flowing systems, and to characterize pollutants resulting from both point and non-point sources present over wide areas. DIRECT ANALYTICAL METHOD FOR AROMATIC COMPOUNDS IN WATER BY STEAM CARRIER GAS CHROMATOGRAPHY,
Yokohama National Univ. (Japan). Dept. of Safety and Environmental Engineering.
K. Urano, H. Maeda, K. Ogura, and H. Wada.
Water Research, Vol 16, No 3, p 323-327, March, 1982. 9 Fig, 2 Tab, 11 Ref.

Descriptors: *Water quality, *Water analysis, Chromatography, Measuring instruments, *Gas chromatogrphy, *Aromatic compounds, Hydrocarbons, Chemical analysis, Wastewater treatment, Industrial wastewater.

Steam carrier gas chromatography was used to determine the presence of various aromatic compounds in water. A hydrogen flame ionization detector was used with acid washed Chromosorb P modified with 3.5 wt% phosphoric acid as a stationary solid-in-glass column. The aqueous solutions of typical aromatic compounds including mono- and di-substituted, benzenes, naphthalene and naphthol, and wastewater from an oil refinery and its treated water were used as samples in this study. The results indicated that various aliphatic and aromatic compounds in water could be directly analyzed by the SCGC method. Water samples from the oil refinery were analyzed after only filtration with 0.45 micrometer membrane. There were six or more compounds in the raw wastewater, and several compounds remained in the water after treatment. The compounds in the wastewater included methyl alcohol, ethyl alcohol, phenol, o-, m-, and p-cresols, and one unknown, which was characterized as a polar low molecular weight aliphatic compound. The wastewater treatment system being used at the refinery was effective only in removing the phenol and cresols. Thus SCGC is a useful technique for evaluating water quality and water treatment processes. (Baker-FRC)

EVALUATION OF METHODS FOR THE ASSAY OF RADIUM-228 IN WATER,
National Bureau of Standards, Washington, DC. National Measurement Lab.
J. R. Noyce.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-178162, Price codes: A02 in paper copy, A01 in microfiche. NBS Technical Note 1137, February 1981. 18 p, 1 Tab, 38 Ref.

Descriptors: *Radium radioisotopes, *Water analysis, *Drinking water, *Radiochemical analysis, Chemical analysis, Assay, Water quality, Water pollution.

Radium-228 is ingested primarily by the drinking of water, and it is hazardous to human health. It has been found to occur in higher concentrations than radium-226 in water in contact with some geological formations. Radium-228 is difficult to assay accurately, especially at low concentrations, because it emits only very low-energy conversion electrons and low-energy beta particles. The technical literature from 1967 to May 1980 was searched for methods for assaying radium-228 in water, and these methods were evaluated for suitability as potential EPA reference methods for drinking water assays. Most of the assay methods were eliminated from consideration by applying

the following criteria: adequate sensitivity, yield determination without radioactive tracers, and a waiting time for ingrowth or decay of radionuclides in the sample of no more than 30 days. It is suggested that the EPA retain the present reference method (Krieger, 1976) but improve its decontamination factor for Y-90 and correct its chemical yield calculation. The McCurdy and Mellor (1979) method should be added as a second reference method. The two procedures complement each other. (Moore-SRC)

DYNAMICS OF THE NUMBER OF BACTERIA AND CONVERSION OF READILY OXIDIZABLE SUBSTANCES IN SMALL RIVERS,
Tallin Polytechnic Inst. (USSR).
A. E. Saava.
Water Resources, Vol 8, No 2, p 195-201, March-April, 1981. 3 Fig, 2 Tab, 12 Ref. Translated from Vodnye Resursy, No 2, p 144-150, March-April, 1981.

Descriptors: *Bacteria, *Indicators, *Self-purification, *Wastewater pollution, *Estonia, Streams, Biological oxygen demand, Bioindicators, Coliforms, Enteric bacteria, Temperature effects, Water temperature, Saprophytic bacteria, Water quality, Fate of pollutants.

Bacterial indicators in wastewater pollution (saprophytes, coliforms, and enterococci) were determined upstream and downstream of wastewater outfalls in small (discharge < 30 cu m per sec) unpolluted Estonian streams. Samples were also collected in winter and summer to study temperature dependence. Relationships between saprophytes, coliforms, and enterococci were found at upstream sites. In winter saprophyte numbers were positively correlated with BOD and with ammonia and nitrite concentrations. Coli index and enterococci numbers were negatively correlated with water temperature, indicating longer survival of bacteria at lower temperatures. In summer the bacterial indicators did not correlate among themselves or with chemical water quality parameters. At downstream sites in winter there were more saprophytes and enterococci than in summer. This was caused by slow dieoff of bacteria at low temperatures. There was a positive correlation between the three bacterial indicators, BOD, and chloride levels. In summer downstream samples, bacterial indicators were postively correlated with the ammonia levels and negatively correlated with dissolved oxygen. A study of bacterial population dynamics in the self-purification process showed that enterococci and E. coli 015 did not multiply in river water at temperatures of 0 to 20 C. Other E. coli strains grew rapidly at higher water temperatures, 10 to 50 C. In summer more than 95% of bacteria died within the first 12-15 hours, and microbial self-purification was completed in about 24 hours. In winter only 70% of bacterial died within the first 12 hours and 95% by the end of the second day. Equations are given, relating the coefficient of death rate of bacteria to temperature or current velocity. (Cassar-FRC)

CHARACTERIZATION OF INDUSTRIAL WASTES BY EVALUATING BOD, COD, AND TOC,
O'Brien and Gere Engineers, Inc., Syracuse, NY.
D. R. Hill, and S. J. Spiegel.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2704-2708, November, 1980. 1 Fig, 4 Tab, 5 Ref.

Descriptors: *Industrial wastes, *Oxygen demand, Mathematical studies, Biochemical oxygen demand, Chemical oxygen demand, Water analysis, Oxygen, Wastewater treatment, Wastewater, Evaluation, *Onondaga, *New York.

Substantial cost and manpower could be saved if any of the three parameters BOD, TOC and COD could be accurately estimated by calculation from the analytical value of one of the others. An examination was undertaken to discern any consistent relationships between these parameters as part of an intensive industrial waste survey in Onondaga County, New York. Data for the study were generated from samples collected from 1973 through mid-1977. About 95% of the samples collected were composites over the production periods of each industry. Relationships were sought between BOD, COD, and TOC using a measurably larger data file, in some industrial waste categories, than had been reported in earlier literature. In these high-data Standard Industrial Classification (SIC) categories, the correlations were sometimes found to be within the 99% significance level, thus permitting extrapolations from only one observed value and reducing the need for and cost of continued testing. (Baker-FRC)

SAMPLING AND ANALYZING WATER,
J. Lehr, T. Gass, W. Pettyjohn, and J. DeMarre.
Water Well Journal, Vol 36, No 2, p 46-51, February, 1982. 1 Tab, 3 Ref.

Descriptors: *Water analysis, *Sampling, Sample preparation, Water quality, Chemical analysis, Public health, Bacteria, *Water supply, Drinking water, *Domestic water.

The process of sampling and analysis of domestic water supplies not only evaluates the cause of a particular problem but also determines the kind of treatment and the size of the equipment needed to provide clear, safe, palatable water in desired quantities. Sampling and analysis of water may also become in some localities a prerequisite for meeting local laws concerning water. A sanitary survey locates potential sources of water quality degradation in and around the point of water withdrawal and determines whether special chemical or biological tests are needed to identify potential sources of pollution. To many homeowners, the most important consideration about any water supply is its freedom from disease-producing organisms. Water must be sampled periodically and be analyzed for bacterial contamination. Various chemical elements and compounds may also be present in groundwater. The sources of these chemicals are associated with either natural processes or human activities. To obtain an adequate sample of water for either biological or mineral analysis, the objectives of the sampling must first be established. Once the purpose is established, the sample taken must accurately represent the quality of the water source. Methods for collecting, preserving, packaging, identifying, and shipping sample bottles and containers for bacteriological analysis are highlighted. (Baker-FRC)
W82-05263

SAMPLING FREQUENCY OPTIMIZATION USING A WATER QUALITY INDEX,
Oregon State Dept. of Environmental Quality, Salem.
D. A. Dunnette.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2807-2811, November, 1980. 5 Tab, 7 Ref.

Descriptors: *Water quality, *Evaluation, *Monitoring, Sampling, Mathematical equations, Water pollution control, Water analysis.

This work describes a water quality index and how it can be used in a very simple way to evaluate and upgrade present monitoring programs. While a complete and thorough theoretical statistical evaluation of an ambient water quality monitoring network is often beyond the resource capability of a state water quality control agency, use of two assumptions can simplify the statistical processes greatly. These two assumptions are: that future water quality statistical data will correlate fairly well with present data, and that data obtained in the water quality monitoring program are normally distributed, i.e., the data describes the classical bell curve. A study was made of the distribution of Oregon Water Quality Index values over a 6 year period, 1972-1977. The simplification suggested in this paper was justified, particularly when the sampling frequency evaluation is considered an interim step prior to a more rigorous evaluation. The simplified approaches to sampling frequency determination indicate a range of between 25 samples per year for a lower water quality station and 6 per year for a higher water quality station, assuming 95% confidence and 5% allowable error. It is emphasized that these sampling frequences are based on observed variability in the OWQI and indicate the number of samples required to meet the confidence and error limits imposed. (Baker-FRC)

Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224791, Price codes: A03 in paper copy, A01 in microfiche. Technical Report No 22, April 1981. 34p, 12 Fig, 4 Tab, 19 Ref, 3 Append. OWRT A-015-GUAM, 14-34-001-0112.

Descriptors: *Water quality, *Municipal wastes, *Water analysis, *Water resources development, *Guam, Water quality standards, Bacterial analysis, Chemical analysis, Wells, Groundwater availability, Groundwater contamination, Resources development, Water supply development, Evaluation, Drinking water, Potable water, Water distribution, Environmental protection, Environmental quality, Environmental policy.

This water quality study assessed the potential of Agana Springs for possible development as a municipal water source. The results indicated that water quality was sufficiently high to merit development of Agana Springs as a freshwater resource. The chemical and physical quality of the water within the impoundment was found to be high relative to the Guam EPA standards for drinking water and standing waters used for drinking water. The observed quality was also higher than many wells and surface water sources currently used by the Guam water distribution system. The observed light-to-moderate bacterial contamination (thought to be due to surface runoff and animal activities and not to contaminated groundwater) could be controlled by chlorination. The results of thirteen chemical and bacterial parameters analyzed over a five-month study are reported and discussed. It is recommended that Guam's government should attempt to obtain the Agana Springs resource for development if the Navy does not plan to develop it for its own needs. Tapping this resource would augment the northern well field with a volume equal to or greater than 4-6 high-production groundwater wells. (Zielinski-MAXIMA)

FLUORESCENCE CELL DESIGN AND USE TO DETERMINE CRUDE OIL IN WATER,
Heriot-Watt Univ., Edinburgh (Scotland). Dept. of Chemistry.
P. John, E. R. McQuat, and I. Soutar.
Analyst, Vol 107, No 1271, p 221-223, February, 1982. 2 Fig, 2 Ref.

Descriptors: *Fluorescence, *Oil, Crude oil, Water analysis, *Pollutant identification, Technology.

A commercial fluorescene cell was modified for use in measuring fluorescence emission from water-dispersed crude oil. A 1 cm path length quartz fluorescence cell was altered to accommodate two concentric inlet tubes and a co-linear exit tube. Maximum flow rates for this cell were 160 cu cm per sec for the sample flow and 504 cu cm per sec for the outer concentric flow. The upper flow guides were adjustable in the vertical direction, allowing establishment of laminar flow after the flow guide was lowered until coincident with the fixed exit tube. They prevented contamination of the optical surfaces. In sufficiently dilute solutions, fluorescence emission intensity for oils of differing characteristics was linearly related to the concentration in non-quenching organic solvents. This relationship was also valid for three crude oils in water, tested at concentrations up to 10 microliters per liter. (Cassar-FRC)

DETERMINATION OF ULTRATRACE LEVELS OF FLUORINE IN WATER AND URINE SAMPLES BY A GAS CHROMATOGRAPHIC/ATMOSPHERIC PRESSURE HELIUM MICROWAVE INDUCED PLASMA EMISSION SPECTROMETRIC SYSTEM,
Tokyo Univ. (Japan). Dept. of Chemistry.
K. Chiba, K. Yoshida, K. Tanabe, M. Ozaki, and H. Haraguchi.
Analytical Chemistry, Vol 54, No 4, p 761-764, April, 1982. 3 Fig, 4 Tab, 27 Ref.

Descriptors: *Fluorides, *Pollutant identification, Trace levels, Seawater, *Gas chromatography, Fluorine, Water analysis.

Fluoride was determined in seawater, tap water, and pond water at concentrations as low as 0.2 micrograms per ml. After extraction with trimethylchlorosilane and conversion to trimethylfluorosilane, the sample was injected into a gas chromatograph and detected by atmospheric pressure helium microwave induced plasma (MIP) emission spectrometry. The emission line of fluorine at 685.6 nm was used for detection. Results from the fluoride ion selective electrode method were comparable with those from the MIP method. Interferences of other ions were studied in samples containing 1 microgram F per ml. Aluminum at 100 micrograms per ml interfered, but the major and minor species found in seawater did not interfere at levels normally present in seawater. (Cassar-FRC)

SAMPLE DIGESTION PROCEDURES FOR SIMULTANEOUS DETERMINATION OF ARSENIC, ANTIMONY, AND SELENIUM BY INDUCTIVELY COUPLED ARGON PLASMA EMISSION SPECTROMETRY WITH HYDRIDE GENERATION,
National Enforcement Investigations Center, Denver, CO.
D. D. Nygaard, and J. H. Lowry.
Analytical Chemistry, Vol 54, No 4, p 803-807, April, 1982. 2 Fig, 8 Tab, 11 Ref.

Descriptors: Metals, *Wastewater analysis, Sample preparation, *Pollutant identification, *Arsenic, *Antimony, *Selenium, Spectrometry.

Persulfate digestion in acid solution followed by heating at 95C in 6M HCl was the best of five sample digestion techniques to prepare water samples for simultaneous determination of arsenic, antimony, and selenium at the microgram per liter level by hydride generation and plasma emission detection. Other, less effective, digestion procedures were nitric acid/sulfuric acid, hydrogen peroxide/sulfuric acid, hydrogen peroxide/nitric acid, and nitric acid. Test samples contained dissolved inorganic, dissolved organic, and suspended particulates. Modifications to the hydride generation apparatus allowed simultaneous generation and detection of the hydrides. Spiked and unspiked wastewater effluent samples from a variety of industrial sources and a sewage plant were analyzed for As, Sb, and Se by the method described in this paper and by the graphite furnace atomic absorption. Results from the two methods were comparable. (Cassar-FRC)

DETERMINATION OF METALS IN GROUNDWATERS BY TRACE ENRICHMENT AND LIQUID CHROMATOGRAPHY,
Atomic Energy of Canada Ltd., Chalk River (Ontario).
R. M. Cassidy, S. Elchuk, and J. O. McHugh.
Analytical Chemistry, Vol 54, No 4, p 727-731, April, 1982. 1 Fig, 5 Tab, 14 Ref.

Descriptors: Trace metals, *Metals, Heavy metals, *Pollutant identification, *Path of pollutants, Chromatography, *Groundwater pollution, Water analysis, *Landfills, Cobalt, Leachates.

Trace enrichment and liquid chromatography were used to detect metal ions in groundwater at the ng or pg per ml levels. Samples of groundwater collected in and near a waste management site were enriched using an in-line cartridge containing a strong acid cation exchanger. The enriched solution was then placed in a conventional high performance liquid chromatograph gradient pumping system with variable wave-length detector. Several sample treatments were evaluated. Fuming with nitric acid and ashing were not reliable methods of releasing bound metal ions. Citrate and nitric acid equilibrations did not give quantitative recovery for total metal ion determination. Sample treatment with Co60 irradiation was the best sample treatment in this study; relative standard deviation values for the metals (Co, Ni, Cu, Zn, Pb, Mg) tested with this treatment were 2-10%. (Cassar-FRC)

TRACE ENRICHMENT OF DIFENZOQUAT IN WATER AND ITS DETERMINATION BY REVERSED PHASE HIGH PERFORMANCE LIQUID CHROMATOGRAPHY,
Alberta Environmental Center, Vegreville.
I. Ahmad.
Analytical Letters, Vol 15, No 1, p 27-37, 1982. 3 Fig, 3 Tab, 8 Ref.

Descriptors: *Herbicides, *Chromatography, *Pollutant identification, Difenzoquat, Water analysis.

A simple, reliable, and quick method for the determination of the herbicide difenzoquat (1,2-dimethyl-3,5-diphenyl-1H-pyrazolium methyl sulfate) in water samples used the reverse phase ion pair chromatographic technique. Enrichment was accomplished with a C18 SEP-PAK reverse phase cartridge, using potassium dihydrogen orthophosphate dissolved in acrylonitrile/water (50:50 by volume) as an eluant reagent. Samples were injected into the high performance liquid chromatograph with no further treatment. Ultraviolet detection was performed at 255 nm. Recoveries of the spiked samples were 88-98%. The practical lower detection limit is 2 ppb. (Cassar-FRC)
W82-05362

GAS-LIQUID CHROMATOGRAPHIC DETERMINATION OF SOME CHLORO- AND NITROPHENOLS BY DIRECT ACETYLATION IN AQUEOUS SOLUTION,
Clemson Univ., SC.
J. Mathew, and A. W. Elzerman.
Analytical Letters, Vol 14, No 16, p 1351-1361, 1981. 2 Fig, 3 Tab, 19 Ref.

Descriptors: *Nitrophenols, *Chlorophenols, *Phenols, *Pollutant identification, Water analysis, Gas liquid chromatography, Acetylation.

Trace levels of chloro- and nitrophenols in water were determined by gas liquid chromatography after direct acetylation. The derivatives were formed by adding 10 g $NaHCO_3$ to 250 ml of aqueous solution of phenol compound followed by addition of 1 ml acetic anhydride. After 2 min the derivatives were extracted twice with 10 ml methylene chloride. The extract was concentrated by a nitrogen stream for injection into the gas chromatograph. Recoveries of phenol acetates at a level of 0.8 to 40 ppb ranged from 90 to 120%. Compounds used in the study were 2,4-dichlorophenol, 2,4,6-trichlorophenol, 2-nitrophenol, 4-nitrophenol, pentachlorophenol, and 2-sec-butyl-4,6-dinitrophenol. (Cassar-FRC)

OVERESTIMATION OF ORTHOPHOSPHORUS CONCENTRATIONS IN SURFACE WATERS OF SOUTHERN LAKE MICHIGAN: EFFECTS OF ACID AND AMMONIUM MOLYBDATE,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
S. J. Tarapchak, S. M. Bigelow, and C. Rubitschun.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 39, No 2, p 296-304, February, 1982. 2 Fig, 3 Tab, 21 Ref.

Descriptors: *Phosphorus, Lakes, *Fate of pollutants, *Separation techniques, Phosphates, Phosphorus compounds, Water pollution sources, Molybdenum, Pollutant identification, Nutrients, *Filtration, Organic matter, Inorganic compounds, Water analysis, *Lake Michigan.

Molybdenum blue methods are thought to overestimate orthophosphorus (P04-P) levels in filtered lake water because P04-P is released from bound sources by hydrolysis. Water samples from southern Lake Michigan were analyzed to assess the accuracy of the molybdenum blue technique and to evaluate the potential effects of ammonium molybdate on soluble reactive phosphorus (SRP) determinations. Time-course hydrolysis tests showed that sizeable quantities of P04-P were released from bound sources into solution immediately after the addition of acid molybdate. Molybdate-reactive P04-P could be retained by filters or released from particulate matter into filtrates during filtration. Using the recommended exposure time of 30 sec, P04-P levels were overestimated minimally by up to 86% and ammonium molybdate increased P04-P release in filtered samples. Other tests employing up to a fourfold range in ammonium molybdate concentrations indicated that Harvey's method and the extraction procedure gave SRP values that varied two- to three-fold or more, with most of the P04-P release originating from particles in filtrates. While the chemical composition of the SRP pool in lake water is not well known, potential sources of particulate P04-P in Lake Michigan filtrates could include large organic molecules or their fragments, colloidal inorganic-organic complexes, or capsular or fibrillar material produced by microorganisms. VARIATION IN FECAL POLLUTION INDICATORS THROUGH TIDAL CYCLES IN THE FRASER RIVER ESTUARY,
Department of the Environment, Vancouver (British Columbia). Inland Water Directorate (Pacific Region).
L. M. Churchland, G. Kan, and A. Ages.
Canadian Journal of Microbiology, Vol 28, No 2, p 239-247, February, 1982. 7 Fig, 15 Ref.

Descriptors: *Tidal rivers, *Variability, *Indicators, Fate of pollutants, *Fraser River, Estuaries, Sampling, Feces, *Coliforms, Bacteria, Shellfish farming, Coprostanol, Sterols, *British Columbia, Canada.

Four sites in the Fraser River estuary were sampled over a 24 hour period and the water analyzed for fecal pollution indicators. Maximum concentrations of fecal sterols and coliforms occurred after high tide at the station upstream of major sewage

outfalls and on the ebb or low tide at stations downstream of the sewage outfalls. Fecal coliform counts were highly correlated with coprostanol and cholesterol levels at sites near sewage plants. In summer fecal coliform counts, but not sterol concentrations, were reduced by chlorination of sewage plant effluent. Fecal sterols may serve as useful indicators of sewage pollution, especially in shellfish harvesting waters and where bacterial determinations require concentration of large volumes of water. Monitoring of fecal pollution in these waters should be done randomly and frequently enough so that the tidal variations are included. (Cassar-FRC)

THE DETERMINATION OF HEAVY METALS (AL, MN, FE, NI, CU, ZN, CD, AND PB) IN URBAN SNOW USING AN ATOMIC ABSORPTION GRAPHITE FURNACE,
Toronto Univ. (Ontario). Dept. of Chemical Engineering and Applied Chemistry.
S. Landsberger, R. E. Jervis, S. Aufreiter, and J. C. Van Loon.
Chemosphere, Vol 11, No 3, p 237-247, 1982. 1 Fig, 2 Tab, 31 Ref.

Descriptors: *Metals, *Snow, *Urban areas, *Pollution identification, Heavy metals, *Montreal, Quebec, Water pollution sources, Air pollution, Canada.

Snow from the island of Montreal, Quebec, contained the following average quantities of trace metals (in nanograms per g): Al, 69; Mn, 11; Fe, 40; Ni, 43; Cu, 28; Zn, 94; Cd, 6; and Pb, 8. An atomic absorption graphite furnace was used for the determinations. Analysis of enrichment factors suggested that Al, Mn, and Fe are normal components, while Ni, Cu, Zn, Pb, and especially Cd were anthropogenically derived. Total annual trace metal deposits by rain and snow in metric tons per year were at Al, 31, Mn, 5; Fe, 18; Ni, 19; Cu, 13; Zn, 42; Cd, 3; and Pb, 4. (Cassar-FRC)
W82-05397

DETERMINATION OF MUTAGENIC POTENTIAL AND ORGANIC CONTAMINANTS OF GREAT LAKES DRINKING WATER,
Department of National Health and Welfare, Ottawa (Ontario).
D. T. Williams, E. R. Nestmann, G. L. LaBel, F. M. Benoit, and R. Otson.
Chemosphere, Vol 11, No 3, p 263-276, 1982. 3 Fig, 8 Tab, 19 Ref.

Descriptors: *Mutagens, *Organic compounds, Drinking water, *Pollutant identification, Water analysis, Pesticides, Chlorinated hydrocarbons, Seasonal variation, *Great Lakes, Polyaromatic hydrocarbons, Alkylaryl phosphates, Aromatic compounds, *Canada.

Ion exchange resin extracts of municipal drinking water from 12 Great Lakes communities were tested for mutagenic potential using the Salmonella/mammalian microsome assay. The samples were also analyzed for organochlorine pesticides, organoposphate pesticides, polyaromatic hydrocarbons, trialkylaryl phosphates, and volatile organic compounds. Dose-related increases in mutagenicity were found in extracts from 11 of the 12 water supplies. Summer samples were more mutagenic than winter samples. No relationships between mutagenic activity and the presence of individual or groups of chemicals could be deduced. Polyaromatic hydrocarbon levels were higher in winter than in summer and were higher in river water than in lake water. Of the organochlorine compounds only alpha- and beta-BHC were detected. Levels were 20 and 8 ng per liter, respectively, or less. No organophosphate pesticides were detected in samples. Trialkylaryl phosphate concentrations were similar in winter and summer samples and increased through the system from Lake Superior to Lake Ontario. Volatile organics concentrations were on the order of those found in previous studies. (Cassar-FRC)

EFFLUENT ANALYSIS OF WASTEWATER GENERATED IN THE MANUFACTURE OF 2,4,6-TRINITROTOLUENE, 2. DETERMINATION OF A REPRESENTATIVE DISCHARGE OF ETHER-EXTRACTABLE COMPONENTS,
SRI International, Menlo Park, CA.
R. J. Spanggord, and B. E. Suta.
Environmental Science and Technology, Vol 16, No 4, p 233-236, April, 1982. 1 Fig, 2 Tab, 4 Ref.

Descriptors: *Chemical wastewater, *Trinitrotoluene, *Wastewater analysis, Cluster analysis, *Pollutant identification, Statistical analysis, Phenols, Industrial wastewater, Organic compounds, Phenols, Nitrotoluenes, Nitrobenzenes, *Explosives, Aromatic compounds.

The distribution of components in a TNT manufacturing wastewater was characterized by cluster analysis and by the 90th percentile approach. Both methods gave comparable results. The major components were 2,4-dinitrotoluene (43-49%), 2,6-dinitrotoluene (21%), and 1,3-dinitrobenzene (12-41%). Constituents comprising between 1 and 5% by either method were toluene, 2,3-dinitrotoluene, 2,5-dinitrotoluene, 3,4-dinitrotoluene, 3,5-dinitrotoluene, 1,5-dimethyl-2,4-dinitrobenzene, 3-amino-2,4-nitrotoluene, 3-amine-2,6-nitrotoluene, 4-amino-2,6-nitrotoluene, 5-amino-2,4-nitrotoluene, and 2,4,6-trinitrotoluene. Sixteen other compounds were present at less than 1%. (Cassar-FRC)

EFFLUENT ANALYSIS OF WASTEWATER GENERATED IN THE MANUFACTURE OF 2,4,6-TRINITROTOLUENE. 1. CHARACTERIZATION STUDY,
SRI International, Menlo Park, CA.
R. J. Spanggord, B. W. Gibson, R. G. Keck, D. W. Thomas, and J. J. Barkley, Jr.
Environmental Science and Technology, Vol 16, No 4, p 229-232, April, 1982. 1 Fig, 1 Tab, 14 Ref.

Descriptors: *Chemical wastewater, *Trinitrotoluene, *Wastewater analysis, *Pollutant identification, Industrial wastewater, Organic compounds, Phenols, Nitrotoluenes, Nitrobenzenes, *Explosives, Aromatic compounds.

Ether extracts of pretreated wastewater from the continuous trinitrotoluene (TNT) manufacturing process were analyzed by glass capillary gas chromatography to characterize the constituents. Samples were collected weekly for 1 year. A total of 32 compounds were identified. The major components, accounting for 75% by weight of the total component distribution, were 2,4-dinitrotoluene, 2,6-dinitrotoluene, and 1,3-denitrobenzene. Also present were N-nitrosomorpholine; N-morpholinoacetonitrile; mono-, di-, and trinitrotoluenes; 1,5-dimethyl-2,4-dinitrobenzene; methyl nitrophenols; amino mono- and dinitrotoluenes; toluene; 1,3,5-trinitrobenzene; 2,4-dinitro-5-methylphenol; 3,5-dinitroaniline; and nitrobenzo-nitriles. Sources of the compounds were suggested. These analyses will aid in toxicologic investigations of this wastewater. (Cassar-FRC)

PORTABLE WATER-WASTES LABORATORY HIGHLIGHTS BENEFITS OF NITROGEN ANALYZING SYSTEMS.
Journal of the American Water Works Association, Vol 74, No 2, p 34, 36, February, 1982.

Descriptors: *Nitrogen, *Laboratory equipment, *Kjeldahl procedure, Pollutant identification, Water analysis, *Wastewater analysis, Automation, On-site tests.

Reduced-size apparatus for measuring nitrogen has enabled the U.S. Army to equip a portable laboratory for on-site analysis of water and wastes. The new Kjeldahl systems fit on a table top, need no hood, and are well insulated. Fully automated operation allows faster processing of samples. The apparatus handles liquid and solid samples from 1 to 250 ml and 0.1 to 10 g, at N levels as low as 0.1 mg per liter. (Cassar-FRC)

PROCEDURES FOR ANALYZING CONTAMINANTS IN DRINKING WATER,
Environmental Protection Agency, Cincinnati, OH.
H. J. Brass.
Journal of the American Water Works Association, Vol 74, No 2, p 107-112, February, 1982. 8 Fig, 7 Tab, 34 Ref.

Descriptors: *Organic compounds, *Water analysis, *Chromatography, Reviews, *Pollutant identification, Drinking water, Laboratory equipment, Chlorinated hydrocarbons.

Many analytical methods are available for determining organic chemicals in drinking water. Sources of contaminants may be natural (humic and fulvic acids), the treatment process (trihalomethanes), point sources (priority pollutants), and nonpoint sources (pesticides). In most cases it is necessary to quantify compounds at the ppb or ppt range. Basic steps in analysis are extraction, concentration, separation, detection and quantitation. Gas chromatography-mass spectrometry and gas chromatography with conventional detectors are useful for low to medium molecular weight compounds. Cost per sample is $100-1500 and $30-500, respectively. High performance liquid chromatography can be used to determine compositions of low to high molecular weight compounds at a cost of $50-500 per sample. Systems for measuring total organic carbon and total organic halogens are available for $9000-15,000 and $9000, respectively. The importance of a quality assurance program is emphasized. The bibliography lists many books, trade publications, and government documents which provide detailed information. (Cassar-FRC)

PROCEDURE FOR CALCULATING THE COMPLEX RANK INDEX OF WATER QUALITY,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
N. A. Gavrishova.
Hydrobiological Journal, Vol 17, No 1, p 87-90, 1981. 2 Tab, 2 Ref.

Descriptors: *Water quality, *Classification, Bacterial analysis, *Water analysis, Chemical analysis, Chemical composition, Water properties, Biological properties, *Technology, *USSR.

A method has been proposed for the rank assessment of the set of hydrochemical, bacteriological, hydrobiological and saprobiological indices embodied in the classification of surface waters. The approach of the rank processing of the data enables a quantitiative evaluation to be made of the whole set of hydrochemical hydrobiological and bacteriological indices when analyzing water quality in a water body or parts of it. For the complex assessment of the water quality of a given sample typified by the set of indices proposed in the system, the gradations of its scale are estimated in terms of rank numbers from 1 to 9 in a sequence from the most highly pure water to the most highly polluted. A rank assessment is made of each index investigated in accordance with its magnitude and position in the system. The sample is then assessed by the set of ranks. For this purpose the sum of the ranks is computed, the arithmetic mean found, and its value employed in evaluation of the sample in conformity with the gradation of the system. Since, in practice, the composition and properties of the water may come under different gradations in terms of the individual indices of the system, and may be different worth as criteria, complex evaluation using the method of rank indices enables the level of saprobicity to be established with greater certainty than on the basis of individually selected hydrochemical, hydrobiological and bacteriological indices or on the basis of their overall consideration but without the proposed method of rank processing. THE RESPONSE OF SPECIFIC CONDUCTANCE TO ENVIRONMENTAL CONDITIONS IN THE EVERGLADES NATIONAL PARK, FLORIDA,
National Park Service, Homestead, FL.
M. D. Flora, and P. C. Rosendahl.

LIBRARY U. of I., URBANA-CHAMPAIGN

Water, Air and Soil Pollution, Vol 17, No 1, p 51-59, 1982. 5 Fig, 1 Tab, 7 Ref.

Descriptors: *Environment, *Monitoring, Everglades, Florida, Specific conductivity, Conductivity, Evapotranspiration, Seasonal variation, Water quality.

A study was conducted to document present day isoconductivity patterns found throughout Shark Slough under both wet season and dry season conditions, relate these patterns to quantitative change in the delivery of canal water to the slough and geograhic proximity to the S-12 delivery site, and assess the short-term response at a single site to short term environmental changes such as extreme storm events. From October 1978 through September 1979, hourly stage and specific conductance were recorded at a station in central Shark Slough, about 17 km south of the S-12 water delivery structures. A comparative analysis of rainfall input and S-12 water delivery indicates that the study period can be subdivided into 8 hydrologic periods of differing water input character. Factors emerging as important in determining isoconductivity patterns in Shark Slough included the quality and quantity of surface water delivered to the slough, the quantitiative realtionship between the amount of surface water delivery and the amount of direct precipitation, and the effects of interrupted sheet flow within the slough during seasonal drawdown periods. The temporal trend from year to year is primarily dependent on the quality of the surface water delivered to the Slough and can be expected to continue to increase should the specific conductance and cation concentration of the delivery water continue to increase. Minimum and maximum extremes in specific conductance are likely to vary annually, depending on regional rainfall and hydrologic conditions. In a system as complex as the Everglades, it is important to maintain a continuing monitoring program both to detect any change in water quality and to differentiate between changes occurring in response to natural conditions and those produced by human actions. (Baker-FRC)

MUTAGENS, CARCINOGENS AND THE WATER CYCLE,
Severn-Trent Water Authority (England).
R. J. Tye, and W. M. Waite.
Water Pollution Control, Vol 80, No 5, p 600-613, 1981. 4 Fig, 17 Ref.

Descriptors: *Pollutants, *Carcinogens, *Mutagens, Water pollution, Public health, Measurement techniques, Pollutant identification.

Epidemiological studies on the incidence of various types of cancer in genetically similar populations in different environments have indicated that over 80% of cancers have some environmental links. The recent development of simple laboratory tests for mutagenesis provides a powerful tool for the tentative identification of potential carcinogens. Mutagenesis is the induction of inheritable changes in the genetic material of a cell. Since studies have shown that over 90% of carcinogens are mutagens, identifiable mutagens should be investigated further to determine whether or not they are also carcinogenic. Epidemiological techniques and laboratory studies have been used to investigate the possible mutagenic and carcinogenic effects of water sources and the pollutants associated with them. The Severn-Trent Water Authority Mutagenicity Unit has investigated modified bacterial test systems which permit the testing of large sample volumes, increasing the sensitivity of any preliminary screening test. The Unit has identified about 200 organic chemicals in water samples. The haloforms and the polycyclic aromatic hydrocarbons are of greatest interest. Mutagenic responses of these organic chemicals can be induced by a wide range of both raw and treated waters using a tube-fluctuation test procedure without prior concentration. However, before work on the fractionation and identification of active organics can begin, it is desirable to concentrate the organic fraction in the waters. Some concentration techniques are discussed. Mutagenesis testing can be applied either to natural water samples or to material shown to be present in waters by analytical techniques and subsequently tested as pure substances. Possible future applications of mutagenesis testing are described. (Carroll-FRC)
W82-05468

A METHOD FOR THE DETERMINATION OF SULPHIDES IN WATER, SEWAGE AND EFFLUENTS,
Southern Water Authority (England).
D. Ballinger, and A. Lloyd.
Water Pollution Control, Vol 80, No 5, p 648-654, 1981. 4 Fig, 5 Tab, 14 Ref.

Descriptors: *Sulfides, *Pollutants, *Measurement techniques, Water pollution, Effluents, Wastewater, Calibrations.

A previous review of existing methods for the measurement of sulfides concluded that none of the available methods was entirely satisfactory. Major complaints included the failure of the methods to determine sulfides selectively and the need to utilize time-consuming procedures. A sulfide analysis procedure for use on sewage, water, and effluents is proposed which attempts to overcome these problems. The method is designed to identify dissolved inorganic sulfides, including undissociated hydrogen sulfide, hydrosulfide, and sulfide ions, as well as total sulfides, including dissolved inorganic sulfides and other compounds liberating hydrogen sulfide from a cold solution containing 0.5 M hydrochloric acid. The procedure involves bringing the sample to solution vapor equilibrium in a closed flask under controlled conditions, determining the concentration of hydrogen sulfide vapor by means of Draeger tubes, and using a calibration graph to relate the concentration of hydrogen sulfide vapor to the concentration in solution. This procedure allows rapid analysis of sulfide in a wide range of sample types. No physical pretreatment is required to distinguish dissolved sulfide from total sulfide, since such a separation cannot be achieved without significant loss of hydrogen sulfide from solution. The technique was developed for use as a field analysis procedure, and the published data for precision and accuracy may be acceptable for routine environmental analyses. (Carroll-FRC)

A NEW SENSITIVE AND SIMPLE SPOT TEST FOR THE DETECTION OF TERTIARY AMINE POLLUTANTS IN WATER,
Z. H. Coll. of Engineering and Technology, Aligarh (India).
M. Qureshi, H. S. Rathore, and A. M. Sulaiman.
Water Research, Vol 16, No 4, p 435-440, April, 1982. 1 Fig, 4 Tab, 27 Ref.

Descriptors: *Pollutant identification, *Organic compounds, *Organic pesticides, *Toxins, Pesticides, Aminotriazole, Saline water, Industrial wastes, Separation techniques, Organic solvents, Solvents, Detection limits, Water analysis.

A simple, inexpensive and specific spot test for the detection of tertiary amines by citric acid in acetic anhydride has been reported. These compounds frequently occur as water pollutants from the use of pesticides or in industrial wastes. An attempt was made to modify this procedure for the detection of organic pollutants in water. The test solution was prepared in acidic, basic, or saline waters, and citric acid impregnated filter paper was used as the reagent. The detection limits for the pesticides amitrol, azobenzene, bavistin and calixin were 0.04, 40, 2, and 3.2 micrograms/drop, respectively. For the toxins 2,4-lutidine, 2,6-lutidine, nicotinic acid, beta-picoline, and quinoline, the detection limits were 4, 100, 0.04, 0.4 and 100 micrograms/drop, respectively. The spot test coupled with solvent extraction can be used to detect the presence of calixin and azobenzene in water, and is simple enough for field use. (Geiger-FRC)

HIGH RESOLUTION ALPHA SPECTROSCOPY BY LIQUID SCINTILLATION TECHNIQUES,
Maine Univ. at Orono. Dept. of Physics and Astronomy.
E. G. Coombs.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236563, Price codes: A03 in paper copy, A01 in microfiche. M. S. Thesis, August, 1980. 39 p, 15 Fig, 2 Tab, 1 Ref. OWRT B-017-ME(4).

Descriptors: *Radioactivity techniques, *Spectroscopy, *Radium radioisotopes, *Pollutant identification, *Water analysis, Uranium radioisotopes, Radioisotopes, Radiochemical analysis, Radioactivity, Radioactive wastes, Pollutants, Pollution load, Environmental protection, Population exposure, Water pollution control, Groundwater pollution, Water quality, Environmental effects.

The use of high-resolution liquid scintillation spectroscopy is described as an inexpensive and rapid method for the determination of radium-226 (an identified health hazard) and other alpha-emitting radionuclides in environmental water samples. Procedures are reported for measuring radium-226, uranium-238, and uranium-234, affording positive identification, high sensitivity due to pulse shape discrimination, and rapid sample preparation. No environmental water samples examined were found to have measurable levels of radium-226. Nonetheless, radium-226 can be detected, measured, and positively identified down to a level of 4 pCi/liter, with a recovery efficiency of 47%. The method was optimized for environmental radiation measurements by: optimizing the energy resolution; reducing the background by use of pulse shape discrimination; and optimizing the scintillation fluor. Since the extractant used will extract any actinide series element, the instrumentation and techniques developed can be applied to other areas (e.g., mesurement of plutonium and uranium in environmental effects studies of the nuclear fuel cycle). Measurements of the polonium 218, 214, and 210 isotopes, and radon-222, were also made. With the present energy resolution, an alpha energy identification to within 0.4 MeV is possible. A PRAGMATIC APPROACH TO WATER QUALITY MICROBIOLOGY IN A CLEAN RIVER AREA,
North West Water Authority (England), Rivers Div.
G. Dussart.
Environmental Pollution, Series A, Vol 27, No 2, p 97-118, February, 1982. 6 Fig, 4 Tab, 38 Ref.

Descriptors: *Water quality, *Monitoring, Rivers, England, Statistical analysis, Data acquisition, Mathematical studies, Microorganisms, Bioindicators, Ecosystems, Aquatic organisms.

A description is offered of how the microbiota may be used for pollution assessment and results are presented of a typical comparative investigation. The utility of canoical correlation analysis was evaluated. Three river systems in northwest England were evaluated using this technique. In the Ehen, nitrite, phosphate and flow appear to relate to the distribution of diatoms, nomotile green algae and filamentous algae. While a landfill leachate problem exists causing high iron concentrations, the correlation does not identify iron as a significant variable. For the Derwent, phosphate

and biochemical oxygen demand are related to the distribution of most groups except for the blue-green algae. For the nutrient-poor Irt, physical, rather than chemical, variables are important. At a more sophisticated level, canonical correlation may be a robust and useful method of examining the factors which affect the distribution of groups of microorganisms in river ecosystems. TRACE DETERMINATION OF AS(III) AND AS(V) IN NATURAL WATERS BY DIFFERENTIAL PULSE ANODIC STRIPPING VOLTAMMETRY,
Kernforschungsanlage Juelich G.m.b.H. (Germany, F.R.). Inst. fuer Angewandte Physikalische Chemie.
F. G. Bodewig, P. Valenta, and H. W. Nurnberg.
Fresenius' Zeitschrift fur Analytische Chemie, Vol 311, No 3, p 187-191, March, 1982. 2 Fig, 4 Tab, 20 Ref.

Descriptors: *Arsenic, Pollutant identification, Water analysis, Organic matter, Trace metals, Anodes.

Arsenic was determined at trace levels in estuarine water and seawater samples. The method involved depositing arsenic onto a rotating gold electrode at a potential of -0.3V vs. a normal calomel electrode, followed by anodic stripping. For a deposition time of 4 min the detection limit was 0.2 micrograms per liter. As(5+), which is electroinactive, was first reduced to As(3+) by gaseous SO2. Other metals at levels usually found in polluted waters did not interfere. Destroying organic matter with hydrogen peroxide-ultraviolet radiation was not necessary in most samples, but did improve accuracy. At As levels of 2-5 micrograms per liter the relative standard deviation was 6-10%. Complete analysis of a sample required 30 min without the As(5+) reduction step and 75 min with the reduction step. (Cassar-FRC)

Hydrobiological Journal, Vol 16, No 6, p 50-51, 1980.

Descriptors: *Chelation, *Metals, Pollutant identification, Organic matter, Chemical analysis, Natural waters, Fate of pollutants, Chemical composition.

A method for determining mean composition and stability of metal complexes in natural waters is described. It does not give qualitative and quantitative composition. Instead, it measures the concentration of ions not incorporated in complexes (using methods such as ionometric measurements, voltamperometric measurements) and hetotal concentration of complex-forming substances, expressed in terms of the concentration of the metal under investigation. INVESTIGATING POTENTIAL WATER CONTAMINATION BY PETROLEUM-ASPHALT COATINGS IN DUCTILE-IRON PIPE,
Southern Research Inst. Birmingham, AL. Analytical and Physical Chemistry Div.
H. C. Miller, W. J. Barrett, and R. H. James.
Journal of the American Water Works Association, Vol 74, No 3, p 151-156, March, 1982. 2 Fig, 11 Tab, 7 Ref.

Descriptors: *Asphalt, *Pipes, *Polyaromatic hydrocarbons, Pollutant identification, Coatings, Aromatic compounds, Fate of pollutants, Paint, Water pollution sources.

Petroleum asphalt seal coatings inside ductile iron water pipes contributed no significant polyaromatic hydrocarbons (PAH) to the water supply under worst-case conditions in a laboratory test. The experimental apparatus circulated clean water through 10.3 m of 150 mm production line pipe in a closed system. The interior of the pipe was coated with asphalt paint according to ANSI specification A21.4. Flange faces were also coated. The pipe was aged for 1 month after coating. Linear velocity of the water was 0.9 m per sec. Water samples were taken at intervals up to 232 hours and analyzed for benzo(a)pyrene and five other common PAH included in the WHO drinking water standards. The analytical method used was high pressure liquid chromatography with fluorescence detection and gas chromatography-mass spectrometry. The sum of the concentrations of the six specified PAH did not exceed 10 ng in any of the water samples. This was only 5% of the WHO recommended maximum of 200 ng per liter. (Cassar-FRC)

IONIC COMPOSITION OF GROUND WATERS AND THEIR DISTRIBUTION IN KARNAL DISTRICT (HARYANA),
Central Soil Salinity Research Inst., Karnal (India).
R. C. Sharma.
Annals of Arid Zone, Vol 20, No 3, p 209-214, 1981. 2 Fig, 1 Tab, 5 Ref.

Descriptors: *Water quality, *Saline water, *Irrigation water, Water analysis, Karnal District, *India, Conductivity, Sodium, Chemical composition, Pollutant identification, Arid lands.

Water quality in the Karnal district, India, area 8007 sq km, was evaluated by collecting 222 groundwater samples from 107 villages. Analyses included electrical conductivity (EC), cations (Ca, Mg, Na, K) and anions (carbonate, bicarbonate, chloride, sulfate). Five classes of water quality were designated: Class I, EC < 2000 micromhos per cm, residual sodium carbonate (RSC) < 5 me per liter, considered safe for irrigation; Class II, EC < 2000 micromhos per cm, RSC > 5 me per liter, usable as irrigation water if soluble Ca salts are added periodically; Class III, EC 2000-4000 micromhos per cm, RSC < 5 me per liter, usable as irrigation water on light soils or with salt-tolerant crops; Class IV, EC 2000-4000 micromhos per cm, RSC > 5 me per liter, usable as irrigation water by mixing with better quality water and application of gypsum; Class V, EC > 4000 micromhos per cm, usable as in Class IV. About 84% of the waters were classified low sodium and 16% high sodium. (Cassar-FRC)

A SIMPLE SPECTROPHOTOMETRIC TECHNIQUE FOR THE DETERMINATION OF PENTACHLOROPHENOL IN WATER,
Battelle New England Marine Research Lab., Duxbury, MA.
R. S. Carr, P. Thomas, and J. M. Neff.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 477-479, 1982. 1 Tab, 9 Ref.

Descriptors: *Phenols, *Pentachlorophenol, *Water analysis, Organic compounds, *Pollutant identification, Spectrophotometry.

A simple, relatively sensitive, reliable spectrophotometric method for quantifying pentachlorophenol (PCP) in water is described. After HCl treatment to release PCP from salts, the sample is extracted with 10 ml chloroform. Then 2 ml of 200 mM NaOH is added to the chloroform extract and the sample vortexed for 30 sec. Absorbance of the resulting aqueous fraction is measured at 320 nm with a Pye Unicam SP 1800 double beam ultraviolet spectrophotometer. Detection limit varies from 5 to 50 ppb for samples of 1000 ml and 100 ml, respectively. There is a linear relationship between PCP concentrations from the detection limit up to 5 ppm, near the saturation limit of PCP in seawater. Extraction efficiencies are 92-102%. (Cassar-FRC)

USE OF ALGAL FLUORESCENCE FOR AN AUTOMATED BIOLOGICAL MONITORING SYSTEM,
Institute for Water Research Ltd., Dortmund (Germany, F. R.).
G. Benecke, W. Falke, and C. Schmidt.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 385-395, 1982. 5 Fig, 2 Tab, 18 Ref.

Descriptors: *Fluorescence, *Algae, *Bioassay, *Pollutant identification, Herbicides, Photosynthesis, Monitoring, Automation.

A bioassay procedure uses algal fluorescence in stream quality monitoring. Test organisms are Scenedesmus or Chlorella. Conditions and pollutants which retard photosynthesis produce variations in the fluorescence curve of plant materials. A normal fluorescence curve shows an increase in height with time, followed by a slight depression, then a second increase. Photosynthetic inhibitors such as herbicides change fluorescence intensity and produce curve leveling and changes in the first phases of the curve. In the fluorescence measurement cell agal cultures mixed into the filtered water sample under investigation are kept dark for a specified period, then exposed to light. In this work an exposure time of 0.5 sec, 150 watt light source, and dark phase of 10 min are used. The light passes through a blue filter, through the cell, and through a red filter with a transmission maximum at 660 nm. A photomultiplier amplifies the signal and a curve is recorded on the oscillograph. For a permanent record, the curve can be photographed. (Cassar-FRC)

INDICATOR BACTERIA SURVIVAL UNDER LABORATORY CONDITIONS,

LIBRARY U. OF I., URBANA-CHAMPAIGN

Marquette Univ., Milwakee, WI. Dept. of Civil Engineering.
A. E. Zanoni, and J. T. Fleissner.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 500-503, May, 1982. 4 Fig, 1 Tab, 13 Ref.

Descriptors: *Indicators, *Bacteria, *Survival, Pollutant identification, Fate of pollutants, Coliforms, Die-off coefficients, Sampling, Incubation, Wastewater, Population dynamics, Mixing.

Jug tests (in vitro) of indicator bacteria survival were performed using three natural waters, Lake Michigan harbor and beach and Milwaukee River, seeded with settled sewage supernatant wastewater. The 3 incubation methods were: quiescent (no disturbance of jug contents), prior mix (vigorously mixed just prior to sampling), and constant mix. Jugs containing 15 liters of water were incubated at 20 C in a dark closet. No matter how the treatment of samples was varied, the population of bacteria peaked at 1 day after seeding. Significant differences in bacterial survival over a 9-10 day period were seen with the three incubation methods, with the three natural waters, with reseeding every 7 days, and with seed concentrations of 0.17-1%. These results suggest that jug tests should not be used to establish die-off coefficients for indicator bacteria. (Cassar-FRC)

VOLATILE CONSTITUENTS OF THE PRODUCED WATER EFFLUENT FROM THE BUCCANEER GAS AND OIL FIELD,
Houston Univ., TX. Dept. of Biochemical and Biophysical Sciences.
B. S. Middleditch.
Journal of Chromatography, Vol 239, p 159-171, 1982. 7 Fig, 1 Tab, 15 Ref.

Descriptors: *Pollutant identification, *Hydrocarbons, Gas chromatography, Industrial wastes, Alkanes, Volatility, Mass spectrometry.

A procedure is presented for the examination of some 200 volatile liquid hydrocarbons in effluents. The examination is performed on Tenax gas chromatography using an automated purge and trap device and the volatile constituents are then examined by combined gas chromatography-mass spectrometry. Using a bonded-phase fused-silica column, these 200 compounds are resolved and then characterized with the aid of several data manipulation techniques. While the n-alkanes are the individual compounds found in highest concentration, the alkylaromatic hydrocarbons comprise a significant proportion of the total hydrocarbons. (Baker-FRC)

CHEMICAL FRACTIONATION OF HEAVY METALS IN WASTEWATER-AFFECTED SOILS,
Chile Univ., Santiago. Dept. of Chemistry.
E. B. Schalacha, M. Morales, I. Vergara, and A. C. Chang.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 175-180, February, 1982. 2 Fig, 7 Tab, 13 Ref.

Descriptors: *Wastewater irrigation, *Heavy metals, *Fate of pollutants, Metals, Copper, Zinc, lead, Chromium, Nickel, Manganese, *Santiago, *Chile Irrigation, Accumulation, Soil chemistry.

Agricultural soils irrigated for 50 years with wastewaters from Santiago, Chile, contained higher levels of extractable heavy metals than soils irrigated with river water. Three extraction methods were used. Each obtained different proportions of soluble, exchangeable, organically bonded, precipitated, adsorbed, occluded, and primary and secondary minerals. Total concentrations of metals (micrograms per g) in contaminated soils were: Cu, 127-183; Zn, 157-315; Pb, 59-64; Cr, 13-74, and Ni 23.5-24.2. In uncontaminated soils metal levels (micrograms per g) were Cu, 61-175; Zn, 94-140; Pb, 21-46; Cr, 4.5-11; and Ni, 18-25. Natural levels of Mn were high in both contaminated and uncontaminated soils. Extractable fractions varied from 48 to 169% in contaminated soils and 21-60% in uncontaminated soils. Although the metals in nonliable form (organic for Cu and inorganic precipitates for Zn) reduce the leaching potential, a shift in chemical equilibrium can mobilize the metal into plant-available forms. (Cassar-FRC)

Descriptors: *Acid rain, *Reviews, Rainfall, Air pollution, Fallout, Precipitation, Sulfur dioxide, Sulfuric acid, *Water pollution sources, History.

This article reviews several steps in the transformation of the concepts of acid precipitation from the domain of scientific curiosity to the domain of public concern and debate. An historical resume is presented in tabular form of the progress that has been made toward understanding the phenomena connected with man's influence on the chemical climate of the earth and their biological consequences. Contributions are presented in the chronological order of their occurrence, whether or not the work was recognized or accepted at the time. The names of the major scientists, the country in which the research was conducted, and the principal contribution to science or public affairs are presented, with appropriate references when possible. Many features of the acid rain phenomenon were first discovered in the mid-1800s in and around the city of Manchester, England. Contemporary concepts about acid precipitation and its environmental effects originated in three seemingly unrelated fields of science: limnology, agriculture and atmospheric chemistry. Concern about acid precipitation and its ecological effects in North America developed first in Canada and later in the United States, initially centering on the effects of sulfur dioxide exposure and associated acid precipitation and heavy metal deposition in the vicinity of metal smelting and sintering operations, especially near Sudbury, Ontario. VOLATILIZATION RATES OF INTERMEDIATE AND LOW VOLATILITY CHEMICALS FROM WATER,
SRI International, Menlo Park, CA.
J. H. Smith, D. C. Bomberger, Jr., and D. L. Haynes.
Chemosphere, Vol 10, No 3, p 281-289, March, 1981. 2 Fig, 3 Tab, 16 Ref.

Descriptors: *Organic compounds, *Volatility, *Mass transfer, *Fate of pollutants, Phenols, Aromatic compounds, Evaporation, Model studies.

A laboratory procedure for measuring the gas and liquid phase mass transfer coefficients and volatilization rate constants was developed. This method applies to compounds of intermediate and low volatility. The basic procedure for measuring volatilization rates was to prepare a saturated or 10 ppm solution of the chemical, whichever was lower. The oxygen reaeration rate characterized the liquid phase turbulence, and the evaporation rate of water characterized the gas phase turbulence. Data for naphthalene, anthracene, 2,4-dinitrophenol, and 1,3-dinitrobenzene were listed. This model was also used to predict the volatilization rate of the 144 organic chemicals on the EPA priority pollutant list in a natural water body. (Cassar-FRC)

USE OF THE PARTITION COEFFICIENT AS AN INDICATOR OF BIOACCUMULATION TENDENCY OF DYESTUFFS IN FISH,
Ecological and toxicological Association, Basel (Switzerland).
R. Anliker, E. A. Clarke, and P. Moser.
Chemosphere, Vol 10, No 3, p 263-274, March, 1981. 3 Fig, 1 Tab, 23 Ref.

Descriptors: *Dyes, *Fish, *Bioaccumulation, *Partition coefficients, Solubility, Fate of pollutants, Accumulation, Organic compounds, *Chemical wastewater.

The partition coefficient in n-octanol/water is a useful indicator of the bioaccumulation tendency of synthetic organic dyestuffs in fish. Fish bioaccumulation, data, obtained according to experimental procedures specified by the Japanese auhtorities under the 1974 Chemical substances Control Law, was produced by member companies of the Ecological and toxicological Association of the Dyestuffs Manufacturing Industry. Partition coefficients were determined experimentally by the shake flask method and were calculated by one of three methods, depending on the chemical sructure of the dyestuff. Tables list the fish bioaccumulation factors and the experimental and calculated partition coefficients for 74 dyes. Substances with experimental partition coefficients of < 1000 have bioaccumulation factors < 100 and need not be subjected to expensive fish accumulation tests. Since the partition coefficients cannot be determined experimentally for highly lipophilic or hydrophilic dyestuffs, the calculated partition coefficient provides a satisfactory alternative approach. BIOTRANSFORMATION OF N-PHENYL-BETA-NAPHTHYLAMINE TO BETA-NAPHTHYLAMINE IN A LABORATORY SLUDGE SYSTEM,
Food and Drug Administration, Washington, DC. Div. of Chemical Technology.
Y. Ku, and G. Alvarez.
Chemosphere, Vol 11, No 1, p 41-46, 1982. 1 Fig, 2 Tab, 11 Ref.

Descriptors: *Water pollution sources, *Wastewater treatment, Npahthylamine, Biodegra-

dation, Sludge, *Activated sludge process, *Carcinogens, Microorganisms, Laboratory tests.

The purpose of this study was to determine whether beta-naphthylamine (BNA) is produced from N-phenyl-beta-naphthylamine (PBNA) by sludge microorganisms under laboratory conditions. The activated sludge was obtained from a local sewage treatment plant in Lorton, Virginia, and used within 1 hr of receipt. High concentrations of PBNA apparently inhibited the growth of the microorganisms or their degradative abilities. Large amounts of BNA were found in the aqueous phase, suggesting that further biodegradation of BNA is limited. A steady rate of conversion of PBNA to BNA was maintained throughout a 36 hr period of study. It was concluded that, due to the biotransformation of PBNA to BNA, a potent cacinogen in humans, BNA may well be released to the aquatic environment if PBNA enters sewage treatment plants. Descriptors: *Degradation, *Aromatic hydrocarbons, *Solar radiation, *Fate of pollutants, Photolysis, Polycyclic aromatic hydrocarbons, Organic compounds, Humic acids, Kinetics.

Photolysis of 8 polycyclic aromatic compounds and heteroatom analogs was studied in a merry-go-round reactor at wavelengths of 313 and 366 nm as well as in broad spectrum light at $>$ 300 nm and sunlight. Quantum yields (all much less than 1), rate constants, and half lives (from a few minutes to several days) were calculated as a fuction of time of year at 40 degrees north latitude. Ratios of summer to winter rate constants were 25 for benzo(b)thiophene, 7.2 for quinoline, and 2-5 for the other compounds, benz(a)anthracene, benzo(a)pyrene, benzo(f)quinoline, 9H-carbazole, 7H-dibenzo(c,g)carbazole, and dibenzothiophene. Photolysis rates were variably affected by addition of dissolved humus and/or oxygen. No obvious relationships between structure and quantum yield were noticeable. (Cassar-FRC)

MOVEMENT OF DIFFUSE SOURCE POLLUTANTS IN SMALL AGRICULTURAL WATERSHEDS OF THE GREAT LAKES BASIN,
Michigan Agricultural Experiment Station, East Lansing.
R. K. Hubbard, A. E. Erickson, B. G. Ellis, and A. R. Wolcott.
Journal of Environmental Quality, Vol 11, No 1, p 117-123, January-March, 1982. 2 Fig, 4 Tab, 30 Ref.

Descriptors: *Runoff, *Agricultural watersheds, Watersheds, *Fertilizers, Agricultural chemicals, Water pollution sources, Water quality, Rainfall-runoff relationships, Erosion, Nitrogen, Phosphorus, *Soil erosion, Canopy, Throughfall, *Agricultural runoff.

Total losses of sediment, nitrogen and phosphorus and the nitrogen and phosphorus distribution in runoff waters and sediments were investigated over a two year period on a small agricultural watershed in the Great Lakes Basin region. High rates of fertilizer application had been made to the area, which was planted to corn or soybeans. During the study period, two events equaled or exceeded the 20 year expectancy in rainfall intensity, amount, and potential for erosion. Of the sediment lost, 99% was removed during 11 months, and 64-86% was lost during a single April Storm. Total sediment, nitrogen, and phosphorus losses during the period were, respectively, 19.213, 64.9, and 31.5 kg/ha for one watershed and 36.821, 72.8, and 41.2 kg/ha for the other. Evaluation of nitrogen and phosphorus distributions in the sediment and water phases respectively showed that 70-95% and 90-98% of these were carried in sediments, except during winter months. The water phase carried 80% of the nitrogen and 33% of the phosphorus during the winter. The study showed the sediments were enriched in total nitrogen but not in extractable phosphorus relative to soils. Microrelief imposed planted ridges and plant stalks or stubble retarded cross row runoff. Greater runoff was observed on the longer and steeper east-west slope of one watershed. Textural discontinuities in the upper parts of the watersheds promoted lateral seepage, resulting in emergent interflow on intermediate slopes, particularly during winter and early spring thaws. (Baker-FRC)

STREAM TRANSPORT OF NUTRIENTS THROUGH A WETLAND,
Cornell Univ., Ithaca, NY. Dept. of Agronomy.
J. H. Peverly.
Journal of Environmental Quality, Vol 11, No 1, p 38-43, January-March, 1982. 4 Fig, 3 Tab, 12 Ref.

Descriptors: *Wetlands, *Nutrient removal, Nitrogen, Phosphorus, Streams, Potassium, Calcium, Carbon, Seasonal variations, Water quality, Runoff, Nonpoint pollution sources, Pollution load, Water pollution sources, *Nutrients, Sedimentation, Organic soils.

A study was conducted to measure the transport of nutrients downstream from cultivated organic soil inputs and to determine the effect of managed wetlands on the creek load downstream. Oak Orchard Creek, just north of the city of Batavia in Genesee County, New York, was the study site. The Creek flows to the northeast a few kilometers through cultivated upland before entering the 3,000 ha Elba Muckland. Water samples were taken from the middle of the stream, about 15 cm below the surface and upstream of the road bridges. Samples were taken biweekly except during times of ice cover. The Oak Orchard Creek system is close to equilibrium for nitrogen and phosphorus movements, with net differences between years in gains and losses depending on quantity and timing of water movement. This wetland did not, therefore, remove significant amounts of nitrogen or phosphorus from water flowing through it, and actually increased the quantities of potassium, calcium, and carbon in the water over the 2 year study period. Highest loading was associated with highest flows, which occur in the winter and spring. Inorganic nitrogen levels in the outflow from the wetlands may fall below phosphorus levels during July and August as a result of plant utilization and denitrification losses. Biological processes downstream may be nitrogen-limited during the late summer. (Baker-FRC)

EFFECT OF SOIL SLOPE AND RAINFALL CHARACTERISTICS ON PHOSPHORUS IN RUNOFF,
Science and Education Administration, Durant, OK. Southern Plains Watershed and Water Quality Lab.
L. R. Ahuja, A. N. Sharpley, and O. R. Lehman.
Journal of Environmental Quality, Vol 11, No 1, p 9-13, January-March, 1982. 5 Fig, 7 Ref.

Descriptors: *Rainfall-runoff relationships, *Phosphorus, *Chemical composition, *Topography, Soil types, Soils, Soil structure, Runoff, Kinetics, Slopes, Storm runoff, *Phosphorus runoff.

Objectives of this study were to investigate, under controlled laboratory conditions, the effect of slope length, percent slope, soil cover and storm size on average solution phosphorus concentrations of runoff and to relate these effects to the kinetic mechanism of phosphorus release as expressed in a given equation. The results demonstrated that the concentration of solution phosphorus in runoff water is appreciably influenced by slope length, degree of slope, soil cover, and storm size. The degree of slope and soil cover primarily influence the effective soil mass that interacts with rainfall and runoff waters, while the slope length influences both the soil mass and water/soil ratio by determining the overland flow depths and velocities along the slope. The effect of storm size on average phosphorus concentration is a result of the kinetics of phosphorus desorption. The experimental data obtained so far on the influence of the above factors on soil phosphorus release in runoff seem to fit in to the conceptual framework of the equation. However, further work is needed on longer slopes and under field conditions to develop a working model. (Baker-FRC)

WATER QUALITY IN A STREAM RECEIVING DAIRY FEEDLOT EFFLUENT,
Science and Education Administration, Lewis, TN. Dairy Experimental Station.
B. F. Hollon, J. R. Owen, and J. I. Sewell.
Journal of Environmental Quality, Vol 11, No 1, p 5-9, January-March, 1982. 1 Fig, 4 Tab, 12 Ref.

Descriptors: *Animal wastes, *Water pollution sources, Runoff, *Dairy industry, *Feedlot runoff, Feedlots, Farm wastes, Water quality, Flow rates, Surface runoff, *Path of pollutants.

A study was begun in 1975 to determine water quality in a stream both above and below the point of direct discharge of surface runoff and waste water from a 200 cow dairy feedlot operation and to evaluate changes in pollution level at selected distances downstream from the point of discharge. The dairy experiment station consists of 172 ha, with a rolling to steep topography. Soils are primarily clay and silt loams over a limestone substrate. Grab samples were collected at 2 week intervals from stations located 400 meters and 3 km upstream, and 100, 500 and 1200 meters downstream from the point source of discharge. Mean coliform concentrations exceeded the EPA permissible level of 2,000/100 ml at 100 and 500 meters below the point source of discharge, but not at 1200 meters. All other parameters were below the permissible levels, Mean concentrations increased for all parameters except BOC and pH when downstream stations were compared with upstream stations. Concentrations of fecal coliforms, fecal streptococci, BOD and orthophosphate declined significantly at 1200 meters, while other parameters were unchanged or declined slightly. Discharge of effluent into the stream did not appear to have a great effect on water quality, and the value of controlling the discharge would be questionable in terms of improving water quality in the receiving stream. APPLICATION OF AN APPROXIMATE ANALYTIC METHOD OF COMPUTING SOLUTE PROFILES WITH DISPERSION IN SOILS,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
C. W. Rose, F. W. Chichester, J. R. Williams, and J. T. Ritchie.
Journal of Environmental Quality, Vol 11, No 1, p 151-155, January-March, 1982. 3 Fig, 1 Tab, 19 Ref.

Descriptors: *Solute transport, *Model studies, *Leaching, *Fertilizers, Nitrates, Nitrogen, Mathematical studies, Lagrangian coordinates.

This paper presents an approximate analytic method of computing the effects of dispersion, assuming that the mean solute penetration depth alpha is separately determined so that alpha provides a Lagrangian coordinate system for the dispersion calculations. The method is based on theories suggested by DeSmedt and Wierenga and assumes that irregular field boundary conditions can be replaced by a defined equivalent constant-flux boundary condition. The adequacy of this assumption was tested using data on the leaching of nitrogen-15 labeled fertilizer nitrate. The use of the analytic model described gave useful interpretation of the field monolith lysimeter data on the movement of the fertilizer. The study data was collected over 3 years from four undisturbed field lysimeters, each enclosed in an 8 square meter block whose topsoil was Keene silt loam. The approximate analytic equation was developed as follows: the solution of the convection/dispersion equation for a step change in concentration under constant flux boundary conditions was assumed to apply approximately under non-steady conditions using an equivalent constant flux. Then an equation describing convection/dispersion of an initially rectangular concentration pulse was constructed by superposition. (Baker-FRC)

A CONTRIBUTION TO SIMPLIFIED MODELS OF FIELD SOLUTE TRANSPORT,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
C. W. Rose, F. W. Chichester, J. R. Williams, and J. T. Ritchie.
Journal of Environmental Quality, Vol 11, No 1, p 146-150, January-March, 1982. 1 Tab, 19 Ref.

Descriptors: *Solute transport, *Model studies, Nitrates, Nitrogen, *Agricultural chemicals, Fertilizers, Leaching, Irrigation, Irrigation programs.

This paper develops and tests the utility of a simple deterministic model for predicting the movement of the mean depth of solute penetration resulting from application of a non-sorbed and non-transformed solute, such as chloride ions. In situations where a peak is discernible in the solute concentration profile, peak position may be substituted for mean solute penetration depth. Despite transformation of the forms of nitrogen, the model is also tested against field observations on the movement of the leachable or mobile form, nitrite ions. The model appears to give results sufficiently accurate for management of mobile solutes in the field, provided tow major assumptions are satisified: that the end result if infiltration into soil is adequately described by a water budgeting approach using knowledge of the soil's field capacity, and that the solute undergoes no processes other than convection (or mass transport) together with dispersion and diffusion. Such other processes could be chemical transformation or sorption, preferential movement down fissures or voids, or instability effects. In contrast to the leaching of anions such as NO3 and Cl, cations are much more strongly sorbed in general, but then their loss by leaching is less severe. The calculations presented are based on physical theory and are of a simplicity compatible with practical irrigation management. (Baker-FRC)

DECOMPOSITION OF CHELATES LEACHED FROM WASTE DISPOSAL SITES,
Technion-Israel Inst. of Tech., Haifa. Dept. of Agricultural Engineering.
Y. Avnimelech, and A. Raveh.
Journal of Environmental Quality, Vol 11, No 1, p 69-72, January-March, 1982. 2 Fig, 1 Tab, 11 Ref.

Descriptors: *Path of pollutants, *Chelating agents, Chelation, Heavy metals, *Landfills, *Leachates, Sludge, Water pollution sources, Solid waste, Water quality, Drainage, Adsorption.

A simple and reliable method was developed to determine the chelating capacity of leachates and soil solution in a study of the degradation of chelating agents in soil. The method is based on the measurement of the effect of chelating agents on the solubility of calcium carbonate. The decomposition of chelating agents in soil as affected by soil composition and aeration was studied with this procedure. Leachates from most waste disposal sites are rich in organic matter and have the capacity to chelate heavy metals and carry them to different water bodies. Leachates from sanitary landfills have been found to contain up to 900 ppm of iron. Leachate coming out of a sanitary landfill model is shown to be stable under anaerobic conditions. However, if exposed to aerobic conditions the chelation capacity is reduced to 0.1-1% of its initial value within about 10 weeks. Physical adsorption of the chelating agent on clay or calcium carbonate particles does not seem significant. The clear-cut effect of aeration on the decomposition of chelating agents manifests the importance of proper and prolonged aeration of the leachate along its pathway from the waste disposal site to the receiving water body. Direct drainage, under anaerobic conditions, from a waste disposal site into a water body should be avoided. (Baker-FRC)

BIOSORPTION OF HYDROPHOBIC ORGANIC POLLUTANTS BY MIXED MICROBIAL POPULATIONS,
Environmental Research Lab., Athens, GA.
W. C. Steen, and S. W. Karickhoff.
Chemosphere, Vol 10, No 1, p 27-32, 1981. 3 Tab, 12 Ref.

Descriptors: *Bioaccumulation, *Bacteria, *Aromatic compounds, *Fate of pollutants, Organic compounds, Polyaromatic hydrocarbons, Phenanthrene, Pyrene, Accumulation, Solubility, Partition coefficients.

Microbial biosorption or bioaccumulation of aquatic pollutants has received increased attention because of its impact on the environmental fate and effects of hazardous organics in aquatic systems. Biosorption partition coefficients for pyrene and phenanthrene were determined on mixed microbial populations generated from 14 sediments and soils collected in several states. Sorption isotherms were determined by equilibrating aliquots of the stock bacterial suspensions with variable concentrations of aqueous solutions of pyrene or phenanthrene at 25 C. The coefficients, 24600 + 6000 for pyrene and 6340 + 1000 for phenanthrene, were nearly constant for all the microbial populations, regardless of source. Semi-empirical equations were developed to relate biosorption partition coefficients to octanol/water partition coefficients and to water solubility and melting point. It is expected that the equations obtained can be extended to other familites of hydrophobic compounds besides the condensed ring aromatics with little or no coefficient adjustment. (Cassar-FRC)

SULFATE WASHOUT RATIOS IN WINTER STORMS,
Battelle Pacific Northwest Labs., Richland, WA.
B. C. Scott.
Journal of Applied Meteorology, Vol 20, No 6, p 619-625, 1981. 3 Fig, 1 Tab, 11 Ref.

Descriptors: *Sulfates, *Storm runoff, Precipitation, Rainfall, Water pollution sources, *Path of pollutants, Winter storms.

This paper examines washout ratio variability for sulfate deposition during the winter season. The variability of the data is clearly evident and is plotted so as to illustrate the vast range of washout ratios observed. However, specific trends do emerge, such as an apparent relationship between the washout ratio and the precipitation rate. The microphysical processes of precipitation growth exerted a definite influence on the washout ratio. Indeed, by stratifying the data according to dominant mode of precipitation growth, some insight was gained into the complexities of nucleation scavenging and transformation processes. Evidence based on the total number of observations in 15 storms suggested that the number of events which contain rimed snow are about equal to the events which contain unrimed snow. Since the nature of precipitation growth can influence sulfate deposition rated by a factor of 50 or more, it is significant to distinguish between these two dominant growth modes, riming versus vapor deposition. More important is the implication that in spite of a rather detailed theoretical explanation of wet removal, washout ratios for sulfate cannot be reliably predicted to within a fator of 2. Thus, much work clearly remains in identifying and parameterizing sulfate removal mechanisms and rates during storm periods. (Baker-FRC)

BIODEGRADATION OF HAZARDOUS ORGANIC POLLUTANTS,
Illinois Inst. of Tech., Chicago.
J. W. Patterson, and P. S. Kodukala.
Chemical Engineering Progress, Vol 77, No 4, p 48-55, April, 1981. 5 Tab, 15 Ref.

Descriptors: *Biodegradation, *Organic compounds, *Industrial wastewater, Priority pollutants, *Wastewater treatment, Biological treatment, Degradation, *Fate of pollutants, Ozonation, Activated carbon, Adsorption, Bioaccumulation, Accumulation.

Less than half of the 114 known organic priority pollutants occur in industrial effluents with sufficient frequency to warrant broad-scale controls. Those with the highest frequency are phthalates, chloroform, methylene chloride, benzene, toluene, phenol, ethylbenzene, naphthalene, phenanthrene/anthracene, tetrachloroethylene, trichloroethylene, and trichloroethane. Several treatment systems for hazardous organics are available. Air and steam stripping, dependent on the principles of Henry's Law, produce air pollution and contaminated condensates, respectively. Ozone oxidation, activated carbon adsorption, and biological degradation are each effective in destroying some of the compounds on the list. In some cases more toxic compounds are formed in the process. A table lists the degree of removal of many toxic organic compounds by biological treatment systems. Several compounds concentrate in sludge by factors of 5 to 100. These are acenaphthene, 1,2- and 1,3-dichlorobenzene, fluoranthene, naphthalene, N-nitrosodi-n-propylamine, bis(2-ethylhexyl) phthalate, butyl benzyl phthalate, di-n-butyl and di-n-octyl phthalates, dimethyl phthalate, benzo(a)pyrene, benzo(k)fluoranthene, chrysene, acenaphthylene, fluorene, phenanthrene, pyrene, tetrachloroethylene, and toluene. GEOTHERMAL POWER: ACCIDENTAL FLUID RELEASES AND WASTE DISPOSAL,

California Univ., Livermore. Lawrence Livermore Lab.
D. W. Layton, and W. F. Morris.
Chemical Engineering Progress, Vol 77, No 4, p 62-67, April, 1981. 4 Fig, 28 Ref.

Descriptors: *Geothermal power, *Cooling water, *Waste disposal, Water pollution control, *Water pollution sources, *Underground waste disposal, Saline water, Hydrogen sulfide, Boron, Ammonia, Powerplants, Injection wells, Wastewater treatment.

Geothermal power plants are a potential source of environmental contamination through accidental releases of saline geothermal fluids and the disposal of liquid and solid wastes. The composition of geothermal fluids varies according to site, up to 250,000 mg per liter total dissolved solids at Salton Sea, California, and may contain boron, arsenic, lead, hydrogen sulfide, and other toxic substances. A spill of 1300 cu m could contaminate soil water and surface waters. Berms can protect against such accidental releases. The most feasible disposal technique for spent geothermal fluids, the most abundant waste, is injection into underground wells. The solid wastes require disposal in carefully constructed and monitored landfills. The ammonium sulfate recovered from the hydrogen sulfide removal process may be marketed as fertilizer if it is boron-free. Cooling waters for geothermal facilities are obtained from irrigation water, waste agricultural water, and steam condensate from flashed-steam power plants. Treatment to remove the substantial suspended solids and dissolved solids of these cooling waters produces significant quantities of solids. An alternate to evaporation ponds is subsurface injection into an aquifer isolated from potable water supplies. Cooling tower drift is a source of boron which can damage agricultural crops and enter the soil. Boron emissions at a 106 MW facility are estimated at 2273 kg per year. Design of geothermal power facilities must provide for accidental releases of fluid, treatment of spent fluids, proper disposal of toxic wastes and blowdown, and containment of drift. (Cassar-FRC)

UPTAKE OF ARSENIC, CADMIUM, LEAD AND MERCURY FROM POLLUTED WATERS BY THE WATER HYACINTH EICHORNIA CRASSIPES,
Jackson State Univ., MS. Dept. of Chemistry.
F. E. Chigbo, R. W. Smith, and F. L. Shore.
Environmental Pollution, Series A, Vol 27, No 1, p 31-36, January, 1982.. 2 Tab, 18 Ref.

Descriptors: *Monitoring, *Water quality, Cadmium, Lead, Mercury, Arsenic, *Heavy metals, Water pollution control, Plants, *Water hyacinth, *Adsorption.

The ability of the water hyacinth to simultaneously accumulate arsenic, cadmium, lead, and mercury at a relatively high level of exposure was investigated. After cultivation of the plants for 2 days in tanks containing 10 ppm of each of the metals in aqueous solution, the plants were harvested and rinsed with tap water. The leaves and stems were separated and analyzed for each of the metals. The ratio of the concentrations of arsenic and mercury in the leaves to the concentrations in the stems was about 2:1. Cadmium and lead showed a concentration ratio in leaves to stems of about 1:1. Leaf concentration of arsenic was the lowest of the metals at 0.3428 mg/g of dried plant material while the leaf concentration of cadmium was highest at 0.5740 mg/g of dried plant material. Analyses were also made of control plants grown in unpolluted water and of plants grown in Bay St. Louis, Mississippi sewage lagoon. The mercury concentrations of plants grown in the sewage lagoon were significantly different from the control sample, which had a concentration of 0.0700 mg/g of dried plant material. These findings suggest that the water hyacinth can absorb relatively high concentrations of arsenic, cadmium, mercury and lead over a relatively short period of time. Periodic analysis of wild plants should result in a pollution monitor of the water to which the plants are exposed. (Baker-FRC)

Descriptors: *Rivers, *Organic matter, Decomposing organic matter, Detritus, Litter, Municipal wastes, Industrial wastes, *New River, Virginia, *Path of pollutants.

Results are presented of an investigation of organic matter transport in an Appalachian Mountain river. The New River is a sixth order stream flowing partly in the ancient Teas River channel in the Appalachian Mountains and is considered to be the second oldest river in the world. Collections for study were made at two points:near Fries, Virginia, and near Glen Lyn, Virginia. Between these two points were several cities and industries which release effluent into the river. Dissolved organic matter was the most abundant form of organic matter transported at both sites throughout most of the year. For the most part, dissolved organic matter concentrations were similar to values reported or other medium to large rivers. Highest dissolved organic matter values were recorded during low flows, but there was no statistically significant correlation between the concentration and discharge. Fine particulate organic matter concentrations were in general lowest in the winter, somewhat higher in summer, and exhibited sharp peaks in spring and fall. No statistically significant correlations between fine particulate organic matter and river discharge over the year or seasonally were detected. However, fine particulate organic matter concentrations increased 15-fold during a storm. Coarse particulate organic matter concentration was highest during autumnal leaf fall and constituted about 13% of the total particulate organic matter samples. However, coarse particulate organic matter was generally less than 1% of the total particulate organic matter throughout most of the year. It appeared that municipal and industrial treatment facilities between the two study sites supplemented the concentration of dissolved organic matter in the river. (Baker-FRC)

BEHAVIOR OF ORGANIC PRIORITY POLLUTANTS IN THE TERRESTRIAL SYSTEM: DI-N-BUTYL PHTHALATE ESTER, TOLUENE, AND 2,4 DINITROPHENOL,
North Carolina State Univ. at Raleigh. Dept. of Biological and Agricultural Engineering.
M. R. Overcash, J. B. Weber, and M. L. Miles.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224544, Price codes: A06 in paper copy, A01 in microfiche. Report No 171, January, 1982. 94 p, 22 Fig, 24 Tab, 173 Ref. OWRT B-122-NC(6). 14-34-0001-9088.

Descriptors: *Path of pollutants, Pollution effects, Plant growth, Plant toxicity, *Organic compounds, Phytotoxicity, Fate of pollutants, Plant growth, *Water pollution effects, Organic priority pollutants, Di-n-butyl phthalate (DnBP) ester, Toluene, 2-4 Dinitrbphenol.

Detailed literature reviews were performed for three of the organic priority pollutants. These reviews were strictly oriented toward the terrestrial system response, including soil adsorption, microbial decomposition, abiotic losses, plant phytotoxicity and uptake by vegetative species. Data and conclusions from these evaluations can be used directly in land treatment design, in-situ spill cleanup design, and multi-media effects studies on terrestrial systems. Specific soil decomposition experiments were conducted for di-n-butyl phthalate (DnBP) and 2,4 dinitrophenol (DNP). The half life of DnBP when applied at 1,000 - 10,000 ppm (dry soil basis) was in excess of 26 weeks while at 200 ppm t 1/2 is about 12 weeks (the latter is closer to actual land treatment loading rates). For DNP the half life was less than 4 weeks for soil loadings of 5-50 ppm (dry soil basis). Volatilization and abiotic loss rates for DnBP and DNP were also determined. DnBP had less than 5% loss by these mechanisms while DNP losses were greater than 90%. Phytotoxicity studies were conducted on corn, soybean and fescue seeds freshly planted in the chemical-soil mixture. For toluene a significant germination effect was determined at 2000 ppm for corn and soybeans. DNBP affected soybean germination at 200 ppm but not corn (even at 20,000 pm). DNP was the most phytotoxic with germination effects appearing at 80 ppm for corn and 40 ppm for soybean.

ALGAL-AVAILABLE PHOSPHORUS IN SUSPENDED SEDIMENTS FROM LOWER GREAT LAKES TRIBUTARIES,
Clarkson Coll. of Technology, Potsdam, NY. Dept. of Civil and Environmental Engineering.
J. V. DePinto, T. C. Young, and S. C. Martin.
Journal of Great Lakes Research, Vol 7, No 3, p 311-325, 1981. 5 Fig, 3 Tab, 37 Ref.

Descriptors: *Phosphorus, *Sediments, *Algae, Lakes, Rivers, *Great Lakes tributaries, Suspended sediments, Phytoplankton, Selenastrum, Particulate matter, Model studies, Fate of pollutants, Maumee River, Sandusky River, Cuyahoga River, Ohio, Cattaraugus River, Genesee River, New York.

Phosphorus available for algal growth was measured in suspended sediment from 5 tributaries to the lower Great Lakes during March-June 1980. The rivers were Maumee, Sandusky, and Cuyahoga in Ohio and Cattaraugus and Genesee in New York. Both chemical analyses and bioassays under aerobic conditions were performed. An average of 21.8% of total particulate P was ultimately available to Selenastrum capricornutum. Total sediment P (in micrograms P per mg dry weight) and ultimately bioavailable P were higher in the Ohio rivers, mean 1.06-1.25 and 6.1-19.5% of total, respectively. Non-apatite fractions of inorganic P (base- and reductant-extractable) correlated well with levels of available P in the suspended sediment samples. The rate of available P release from the sediments was generally independent of the observed sediment characteristics. Accuracy of model studies on P dynamics may be improved by considering available P to be released from an ultimately available fraction of the total particulate P in the water column rather than the short-term available P. CIRCULAR WALL JETS IN COFLOWING STREAMS,
Alberta Univ., Edmonton.
N. Rajaratnam, and M. J. Stalker.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY2, p 187-198, February, 1982. 10 Fig, 1 Tab, 11 Ref.

Descriptors: *Path off pollutants, *Open channels, *Jets, *Flow velocity, *Mixing, *Mathematical studies, *Flow profiles, Fate of pollutants, Flow discharge, Channel flow, Nozzles, Instream flow, Industrial wastewater.

The diffusion of circular turbulent wall jets for the discharge of industrial or municipal wastewaters into a coflowing stream was studied, with the depth of flow in the range of 20-30 times the nozzle diameter and the jet velocity varying from about 2 to 30 times the mean velocity of the channel flow. Similar distributions were found between the jet longitudinal velocity and the stream velocity in the free mixing region in the channel centerplane. The velocity profiles might be described by a power law that varies the exponent within a band in the boundary layer portion. The jet velocity with respect to the free stream was found to be similar in the transverse direction in the horizontal plane of the maximum velocity. The length scales in the vertical direction and in the transverse direction were correlated using the excess momentum thickness. The velocity and shear velocity scales have also been correlated using the excess momentum thickness. When the ration of the longitudinal distance from the nozzle to the excess momentum thickness is near 5, the present results give good agreement with the corresponding predictions for circular free jets in coflowing streams. For larger values of this ratio, the results are influenced by the presence of the boundary (bed). The freestream gives significant restrictions of the transverse spreading of the jet compared with circular wall jets in stagnant ambients. (Geiger-FRC)

MIGRATION OF RUTHENIUM-106 IN A NEVADA TEST SITE AQUIFER: DISCREPANCY BETWEEN FIELD AND LABORATORY RESULTS,
Lawrence Livermore National Lab., CA.
D. G. Coles, and L. D. Ramspott.
Science, Vol 215, No 4537, p 1235-1237, March, 1982. 1 Fig, 1 Tab, 14 Ref.

Descriptors: *Radioactive wastes, *Groundwater, Wells, Migration, Aquifers, Groundwater movement, Water pollution sources, Nuclear explosions, Ruthenium-106, *Nevada Test Site.

As part of a program to study the interaction of nuclear explosion debris and ground water, events in a flooded nuclear waste repository were also considered. The migration rate of ruthenium-106 in the field was investigated. Water was sampled from a well which intersected the explosion cavity created by detonating a nuclear device at a depth of 294 meters in tuffaceous alluvium. Tritium and strontium-90 were the only radionuclides whose concentrations were above the maximum permitted for unrestricted public use of drinking water, even though the water had been in direct contact with nuclear debris for 10 years. A satellite well was drilled 91 meters south of the explosion point to study migration rates of the radionuclides in the cavity water. Pumping from the satellite well induced a gradient between the explosion point and the well. Ruthenium-106 migrated in ground water at about the same velocity as tritium from the underground explosion site to the pumped satellite. This finding contradicts the predictions of laboratory studies based on batch sorption measurements that ruthenium-106 should migrate at a much lower rate than tritium. To predict migration of radionuclides in groundwater, more relevant laboratory measurements are needed. (Baker-FRC)

UPWARD TREND IN NITRATE CONCENTRATIONS IN RIVER DISCHARGING INTO LOUGH NEAGH FOR THE PERIOD 1969-1979,
Ministry of Agriculture, Belfast (Northern Ireland). Agricultural and Food Chemistry Div.
R. V. Smith, R. J. Stevens, R. H. Foy, and C. E. Gibson.
Water Research, Vol 16, No 2, p 183-188, February, 1982. 5 Fig. 5 Tab, 15 Ref.

Descriptors: *Nitrates, *Rivers, Water quality, Public health, Drinking water, Phytoplankton, Municipal wastewater, Land use, Farming, *Water pollution sources, *Lough Neagh, *Northern Ireland.

Results are reported of a discrete sampling program of the nitrate concentrations in the major rivers discharging into Lough Neagh for the period 1969-1979. An attempt was made to assess causal factors for the increase in nitrate concentration observed by examining the trends in land usage, drainage, agricultural practices and human population over the study period. The Lough Neagh catchment has a total size of 4453.4 square kilometers, with average rainfall of 1028 mm. Six inflow rivers drain 88% of the catchment. Soil material is mostly basaltic glacial till, and the principal soil associations are climatic peat and acid brown earths and gleys on the lowland. The mean nitrate N concentration in the major rivers discharging into Lough Neagh for the years 1969 and 1970 was 1.41 mg nitrogen/liter. For the years 1978-1979 this mean had risen to 2.41 mg nitrogen/liter. One important concern regarding this increased nitrate concentration was the possible increased risk of methemoglobinemia if these waters were consumed directly by infants. However, all present values are well below the permissible nitrate concentration of 11.3 mg nitrogen/liter. A notable feature regarding changes in land use in Northern Ireland during the study period is the reduction in arable farming, which is a continuation of a trend established since World War II. Another factor is the human population changes during the study period. A redistribution occurred between the rural and sewered population. Rural populations declived from 144,000 to 128,000, while the sewered population increased by 25%. Still it seems unlikely that the increase in human sewered population observed could have contributed more than 3.7% increase to the rise in nitrate concentration noted in the present study. (Baker-FRC)

A BUDGET MODEL ACCOUNTING FOR THE POSITIONAL AVAILABILITY OF PHOSPHORUS IN LAKES,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
S. C. Chapra.
Water Research, Vol 16, No 2, p 205-209, February, 1982. 3 Fig. 1 Tab, 23 Ref.

Descriptors: *Lakes, *Phosphorus, Eutrophication, *Model studies, Sediments, Lake Erie, Phosphorus loading, Lake sediments, Suspended sediments.

A budget model for phosphorus loading relationships in lakes is presented. The model takes into consideration the fact that phosphorus may be reintroduced into the water column by wind-induced sediment resuspension in shallow lakes. The model is calibrated with Schaffner and Oglesby's data from lake loading/response relationship studies and is used to simulate in-lake phosphorus levels for the three basins of Lake Erie. The major objective of the model development was to provide a more mechanistic framework for assessing the effect of positional availability on lake eutrophication. An ancillary result was the reintroduction of mean depth as an explicit variable in trophic state assessment. The model as presented accounts for both the rapid settling of allochthonous particles and the slow settling of autochthonous particles that remove phosphorus from the water column. The effect of resuspension of bottom sediments is modeled by making the apparent settling velocity a function of lake depth. The resuspension effect is important for lakes less than 10 meters in depth. (Baker-FRC)

DETECTION OF DIETHYLNITROSAMINE IN NITRITE-RICH WATER FOLLOWING TREATMENT WITH RHODAMINE FLOW TRACERS,
National Fishery Research Lab., La Crosse, WI.
S. L. Abidi.
Water Research, Vol 16, No 2, p 199-204, February, 1982. 2 Fig, 3 Tab, 15 Ref.

Descriptors: *Dyes, *Nitrites, Nitrosamines, Carcinogens, *Tracers, Dye releases, Public health, Environmental effects, Rhodamine B, Rhodamine WT, Diethylnitrosamine, *Path of pollutants.

The results of an investigation of the reaction of nitrite with two commonly used water tracing dyes are reported. The effects of reaction variables on yields of diethylnitrosamine (DENA), including inhibition by ascorbic acid, are described. The optimum pH for quantitative formation of DENA is 5. On either side of 5 the yields decreased. The more favorable nitrosation occurred at a higher level of nitrite relative to the starting amine, at a more elevated temperature, and at a longer duration of reaction. A yield as high as 75% was realized when the reaction was run with a large excess of nitrite in pH 5 buffer at 80 degrees C for 12 hr. Under identical conditions, the DENA yield from Rhodamine WT was at least twice that obtained from Rhodamine B. It is suggested that the additional carboxy group in the former accelerated its conversion into the nitrosamine. Ascorbic acid effectively inhibited nitrosation. Experiments were also made on environmental samples. Samples were collected and pH's and nitrite-nitrate contents measured. Samples were taken and treated with Rhodamine flow tracer at levels of 1, 10 and 20 micrograms/liter. Mixtures were stirred gently with and without added nitrite. The dichloromethane extracts of each of the nitrosated mixtures were then purified and analyzed for DENA. The levels of nitrite present in local stream water were thus monitored weekly by sampling top and bottom river water . Photodegradation of DENA formed in river water samples containing the Rhodamine dye and nitrite proceeded somewhat sluggishly. The finding that red fluorescent water tracing dyes can react with nitrite in natural water to form the carcinogenic DENA is cause for concern. (Baker-FRC)

INDIA: EVERY RIVER POLLUTED, AND FEW EFFECTIVE CONTROLS,
D. J. Davidar.
Ambio, Vol 11, No 1, p 63-64, 1982.

Descriptors: *Water pollution control, *Legal aspects, *Water pollution sources, *India, Water pollution, Drinking water, Municipal wastes, Industrial wastes.

Every major river system in India is polluted. Although the major part of the pollution is caused by biodegradable domestic wastes, heavy metals such as mercury, cadmium, nickel, manganese, lead, chromium, copper and antimony have been found in rivers in Gujarat, Rajasthan, Bihar, Maharashtra, Kerala and Andhra Pradesh. All the rivers have industrial pollutants discharged into them by industries. Toxic wastes are indiscriminately dumped on land as well. What aggravates the problem of land and water pollution is the seasonal monsoon rains. When the rains fall the stockpiled wastes are leached into thee groundwater reservoirs which are used for drinking pur-

poses. Any wastes dumped into the smaller rivers become highly concentrated when the rivers dry up. Sanitary conditions in the entire country are minimal. Only 8 of the more than 3000 cities in India have complete sewage facilities, leading to enormous problems. Nuclear and radioactive wastes must also be disposed of in this country. National and state legislation to regulate all the various types of pollution does exist. Under provisions of the Water Pollution Act most State Boards have functions including laying down safe pollution levels for industry, monitoring air and water quality, and prosecuting violators of pollution controls. But the State Pollution Control Boards have not been very effective. When prosecuted, private companies sometimes threaten to close down the factory rather than install pollution control measures. Lack of funds and trained personnel make the job harder. (Baker-FRC)

WEAK CONTROLS FROM SEA TO SHINING SEA,
University of Western Ontario, London. Dept. of Zoology.
D. M. Ogilvie.
Ambio, Vol 11, No 1, p 51-53, 1982. 2 Fig, 7 Ref.

Descriptors: *Hazardous materials, *Waste disposal, Water pollution sources, Groundwater pollution, *Canada, *Legal aspects, *Regulations, Leaching.

A rather low standard of care has been maintained in Canada concerning hazardous wastes, and the results are clearly evident in many parts of the country where improper waste disposal practices have been carried on. The discharge of benzene-containing solvents and mercury-contaminated acids into the sewer system, the presence of mercaptan pesticide in an insecure landfill, the dumping of wastes contaminated with heavy metals and cyanide in municipal dumps, and the contamination of groundwater by leaky dumpsites have been reported. Industry spokesmen claim it is difficult and expensive for many companies to do anything with their wastes except dump them into the sewer system. In the wheat producing province of Saskatchewan an aquifer that supplies drinking water for the capital city of Regina is reported in danger of contamination from a 1976 PCB spill and from chemicals leaching from a landfill site. One proposal to alleviate the situation calls for management of hazardous wastes in western and northern Canada to be done on a regional, rather than strictly provincial, basis. The system would consist of one incineration plant to serve the entire region, with physical-chemical treatment plants in each of the four western provinces and a network of collection stations across the region. Federal control can be applied to environmental hazards which are associated with activities such as fishing and with certain aspects of manufacturing and shipping. Provincial governments have broad legal jurisdiction. However, it is mainly with provincial authority that waste disposal can be controlled. The Canadian legal system has few absolute constraints on government actions to effectively control and regulate hazardous substances. The key question is whether governments will adopt appropriate regulatory policy. (Baker-FRC)

INFILTRATION INFLOW ANALYSIS: FINDING THE SOURCE,
CH2M/Hill, Seattle, WA.
K. T. Holmes, E. Black, and D. E. Brown.
American City and County, Vol 97, No 2, p 23-26, February, 1982.

Descriptors: *Sewer systems, *Infiltration, *Sewer infiltration, *Testing procedures, Stormwater, Runoff, Wastewater collection, *Springfield, *Oregon.

As a first step in the sewer system evaluation survey for Springfield, Oregon, flows in the wastewater collection system were monitored at 54 manhole sites during low and high groundwater conditions. This monitoring revealed that groundwater entered the 165 mile collection system when the water table was above the pipeline invert. It also showed that rainfall caused an immediate and sharp increase in flows. To complete the study, the wastewater collection system was smoke tested to locate sources of storm induced infiltration and direct stormwater runoff entry. From the outset it was recognized that smoke testing is only a detecting technique and cannot be used to quantify the I/I flow rate. It was also noted that smoke testing would not reveal what needed to be repaired in a sewer section without additional field work. Testing also would not reveal the location of a defect between manholes. Also, if smoke is not observed escaping, it does not necessarily mean the manhole-to-manhole segment tested does not have any defects. Dyed water testing was conducted at each of the 79 indicated cross connection locations to determine the exact location of any connection. Use of the dyed water testing with closed-circuit internal television inspection revealed that most of the noted sites were not directly connected. (Baker-FRC)

MOVEMENT AND IDENTIFICATION OF A CREOSOTE-DERIVED PAH COMPLEX BELOW A RIVER POLLUTION POINT SOURCE,
Roswell Park Memorial Inst., Buffalo, NY.
J. J. Black.
Archives of Environmental Contamination and Toxicology, Vol 11, No 2, p 161-166, 1982. 5 Fig, 2 Tab, 6 Ref.

Descriptors: *Creosote, *Sediments, *Rivers, Water pollution sources, Fate of pollutants, Path of pollutants, Polyaromatic hydrocarbons, Aromatic compounds, *Hersey River, *Michigan, Muskegon River, Organic compounds, Hydrocarbons, Wood treatment wastes.

A wood treatment operation abandoned in 1949 was identified as the source of creosote contamination of the Hersey River, Michigan. Creosote from two major spills of 15,000 and 18,000 gal as well as small leaks and drips had permeated the sandy surface soils to an impervious clay layer, then entered the river via springs. Sampling of river sediments at 9 sites and analysis by high pressure liquid chromatography showed a pattern of pollution concentration that decreased in a double exponential curve with distance. The greatest concentrations of polyaromatic hydrocarbons and of the individual compounds monitored (1,2-benzanthracene and 3,4-benzo(a)pyrene) were found directly downstream from the source. Levels were 231,000, 61,669, and 15,817 ng per g (wet basis), respectively. These levels decreased to 352, 1023, and 396 ng per g wet basis, respectively, at 400 decameters from the source. The curve obtained by plotting distance from the source against concentration of contaminants was asymptotic, implying that the river's sediments were polluted over a considerable distance. MODELING OF LEACHATE ORGANIC MIGRATION AND ATTENUATION IN GROUNDWATERS BELOW SANITARY LANDFILLS,
Waterloo Univ., Ontario.
J. F. Sykes, S. Soyupak, and G. J. Farquhar.
Water Resources Research, Vol 18, No 1, p 135-145, February, 1982. 11 Fig, 3 Tab, 33 Ref.

Descriptors: *Leachates, *Landfills, *Organic matter, *Model studies, Sanitary landfills, Chemical oxygen demand, Path of pollutants, Fate of pollutants, Biodegradation, Degradation, Microbial degradation, Garbage dumps, Groundwater pollution.

A model for transport of organic matter, measured as COD, in soils near sanitary landfills is developed. The model treats organic transport in 3 phases. The first models degradation with simultaneous Michaelis-Menten substrate utilization and microbial mass production equations with convection and dispersion included for the former. In the biologically-active zone, suggested by these equations, substantial organic degradation occurs within small distances, often less than 5 meters, even under widely varying conditions. The second phase involves first-order decay. The third phase consists of a nonbiodegradable organic residue which migrates by connection and dispersion. Field studies were conducted at the Canadian Forces Base Borden sanitary landfill, closed in 1976, to provide data for comparison with model predictions. This showed that COD was reduced to about 100 mg per liter after traveling 1 or 2 meters, by biodegradation, not adsorption. A nonbiodegradable component of 50-100 mg per liter concentration was also detected. (Cassar-FRC)

NUMERICAL SIMULATION OF THE TRANSPORT AND SPECIATION OF NONCONSERVATIVE CHEMICAL REACTANTS IN RIVERS,
Commonwealth Scientific and Industrial Research Organization, Ryde (Australia). Inst. of Earth Resources.
B. M. Chapman.
Water Resources Research, Vol 18, No 1, p 155-167, February, 1982. 11 Fig, 5 Tab, 37 Ref.

Descriptors: *Solute transport, *Chemical reactions, *Rivers, *Fate of pollutants, *Model studies, Sedimentation, Chemical precipitation, Suspended solids, Absorption, Ion transport, Speciation, Mine wastes.

A model using the program MINEQL was used to simulate the transport of nonconservative chemical pollutants in flowing water. The processes of precipitation, sedimentation, and adsorption were added to a model of conservative chemical transport. The physical transport submodel used a convolution integral procedure with an approximation form of the impulse function to solve a one-dimensional convective-diffusion equation. Although the model assumed chemical equilibrium, a pseudokinetic treatment was necessary to deal with redissolution of precipitates and dissociation of surface species. Hypothetical examples were given for calcium chloride entering a stream. The model was tested by injecting NaOH into Daylight Creek, New South Wales, Australia, draining an abandoned lead-zinc mine. Concentrations of the metals Zn, Al, Cu, Fe, and Na in the stream water were expressed as total metals and as suspended solids. These were followed as a function of time and distance downstream. Significant sedimentation of the precipitate was noted. Substantial quantities of protons and/or metal ions were absorbed on the stream bed. The model results agreed reasonably with observations. Better results would have been obtained if sedimentation time constants for the five metal precipitates had been individually considered. (Cassar-FRC)

MERCURY CIRCULATION IN AQUATIC ENVIRONMENT. PART 3. MERCURY TRANSFORMATIONS IN SEDIMENTS,
J. Stary, B. Havlik, K. Kratzer, J. Prasilova, and J. Hanusova.
Acta Hydrochimica et Hydrobiologica, Vol 8, No 1, p 29-33, 1980. 1 Tab, 10 Ref.

LIBRARY U. OF I., URBANA-CHAMPAIGN

Descriptors: *Mercury, *Methylmercury, *Sediments, Fate of pollutants, Heavy metals, Metals, Aquatic environment, Chemical reactions, *Czechoslovakia, Reslava Creek, Botic Creek.

Sediment from the Reslava Creek, Czechoslovakia, highly polluted with pulp and chemical wastes, contained an average of 0.19 + or - 0.02 ppm methylmercury (1.05% of total mercury). Sediment from the Botic Creek, polluted with urban sewage, had lower levels of methylmercury, 0.029 0.003 ppm (6.3% of total mercury). Transformation of inorganic Hg, methylmercury, and phenylmercury were studied in the laboratory using Hg203 compounds and sediments incubated by three procedures: (A) in open glass vessels for 28 days, (B) under a nitrogen atmosphere for 28 days, and (C) in test tubes standing in darkness for 42 days. Method (C), most like natural conditions, formed methylmercury at the fastest rates. The equilibrium concentration of methylmercury was dependent on the rates of the two reactions: methylation of inorganic Hg and transformation of organomercury compounds into inorganic Hg. The lower the rate of demethylation, the higher the concentration of methylmercury. During the 14-28 days necessary to reach equilibrium conditions inorganic Hg formed 1.0 to 3.9% organic Hg, methylmercury was reduced to 42-86% of the original content, and phenylmercury was reduced to 35-43% of the original content. FLUXES OF POLYCYCLIC AROMATIC HYDROCARBONS TO MARINE AND LACUSTRINE SEDIMENTS IN THE NORTHEASTERN UNITED STATES,
Indiana Univ., Bloomington. School of Public and Environmental Affairs.
P. M. Gschwend, and R. A. Hites.
Geochimica et Cosmochimica Acta, Vol 45, No 12, p 2359-2367, 1981. 2 Fig, 3 Tab, 50 Ref.

Descriptors: *Hydrocarbons, *Bottom sediments, Marine sediments, Lake sediments, Precipitation, Fluctuations, Aromatic compounds, *Path of pollutants, Cores.

In an effort to quantify the deposition rates for polycyclic aromatic hydrocarbons (PAH) in both remote and urban locales, the PAH abundances in several dated sediment cores from the northeastern United States were determined and the corresponding PAH fluxes to these sites were calculated. Fluxes of 10 of these hydrocarbons were measured for each of six sites for the periods roughly corresponding to the present, 1950, and 1900. Present-day deliveries of individual PAH were consistently close to 1 nanogram per square centimeter per year at remote sites, probably reflecting the atmospheric fallout of these combustion-derived pollutants. The current inputs of individual PAH at sites located nearer to urban centers averaged about 35 nanograms per square centimeter per year, presumably as a result of greater fallout of PAH-laden particles nearer their origins and of runoff delivery of PAH-contaminated sediments. The differences in the relative abundances of individual PAH support assumptions of different delivery mechanisms at urban and at remote locations. Deposition data indicate that current PAH fluxes are 5 to 10 times greater than those of 80 years ago, but that these inputs have diminished by a factor of 2 during the last two decades. EXTRACTABLE ORGANIC MATTER IN MUNICIPAL WASTEWATERS. I. PETROLEUM HYDROCARBONS: TEMPORAL VARIATIONS AND MASS EMISSION RATES TO THE OCEAN,
California Univ., Los Angeles. Dept. of Earth and Space Sciences.
R. P. Eganhouse, and I. R. Kaplan.
Environmental Science and Technology, Vol 16, No 3, p 180-186, March, 1982. 3 Fig, 5 Tab, 33 Ref.

Descriptors: *Municipal wastewater, *Ocean dumping, *Hydrocarbons, Chemical analysis, Petroleum, Organic compounds, Organic matter, *California Bight, Fate of pollutants.

The research presented here is part of a large study aimed at characterizing the terrestrial sources of organic matter to the southern California Bight and constructing a reasonable budget for this coastal system. The majority of southern California's municipal wastewaters receive only primary treatment and are introduced directly to the ocean via submarine outfall systems at a water depth of about 60 meters. During 1979 a series of flow proportioned 24 hr composite samples were collected by personnel at each of four treatment plants. Samples were analyzed for total, aliphatic, and aromatic hydrocarbons. Mean total hydrocarbon contents of those effluents having received mainly primary treatment ranged from 6.1 to 16.3 mg/L, whereas sludge concentrations were about 340 mg/L. The vast majority of these hydrocarbons are associated with particulate matter. However, their composition was virtually identical for all effluents. The temporal variations of wastewater total hydrocarbon concentrations appeared to be independent of sampling frequency. From this data Southern California's treatment plants were estimated to discharge more than 17400 metric tons of hydrocarbons per year or 4.9 grams per capita day to coastal waters. This is about double the input rate due to surface runoff in this same region. It also represents nearly 6% of the worldwide input of wastewater borne petroleum to the ocean. Problems associated with global input assessments are considered, and a correlative means of estimating wastewater hydrocarbon concentrations is presented. (Baker-FRC)

EMPIRICAL TEST OF THE ASSOCIATION BETWEEN GROSS CONTAMINATION OF WELLS WITH TOXIC SUBSTANCES AND SURROUNDING LAND USE,
Rutgers-The State Univ., New Brunswick, NJ.
M. Greenberg, R. Anderson, J. Keene, A. Kennedy, and G. W. Page.
Environmental Science and Technology, Vol 16, No 1, p 14-19, January, 1982. 7 Tab, 11 Ref.

Descriptors: *Well water, *Groundwater pollution, *Land use, *Pesticides, Chlorinated hydrocarbons, *Heavy metals, Water pollution sources, *New Jersey.

In order to get a broad perspective on the spatial distribution of hazardous substances in the environment, it is necessary to explore the relationship between land use and gross contamination by hazardous materials. Data on toxic substances present in water from a sample of 408 wells located throughout the state of New Jersey were used to select the following: the 10 wells most contaminated with light chlorinated hydrocarbons, the 10 wells with the highest levels of pesticides, the 10 wells with the highest levels of heavy metals, and a control group of 10 wells with nondetectable or trace amounts of the 45 toxic pollutants investigated. New Jersey's Land Oriented Reference Data System (LORDS), which provides 21 categories of land use based on aerial photography, was used to identify land uses within a 1 mile radius and within a 10 mile radius of each of the 40 wells selected. Factor analysis showed that the 45 chemicals investigated strongly associated by type and that each of the wells tended to associate with only one of the categories. The Mann-Whitney test and discriminant analysis were used to determine whether any of the four groundwater well groups had significantly different percentages of any of the 21 land uses. Distinctive land-use patterns were found for the 1-mile radius areas surrounding the pesticide and light chlorinated hydrocarbons wells, while the heavy metal and clean well land use profiles were similar to each other. The pesticide wells showed a relative excess of mixed and evergreen forests and agricultural land uses within 1 mile of the well sites, while residential, industrial, utility, commercial, and other urban land uses were dominant in the areas within a 1 mile radius of wells highly contaminated with light chlorinated hydrocarbons. EXPERIMENTAL STUDIES TO DETERMINE THE FATE OF PETROLEUM HYDROCARBONS FROM REFINERY EFFLUENT ON AN ESTUARINE SYSTEM,
Bermuda Biological Station, St. Georges West.
A. H. Knap, and P. J. LeB. Williams.
Environmental Science and Technology, Vol 16, No 1, p 1-4, January, 1982. 5 Tab, 24 Ref.

Descriptors: *Industrial wastes, *Fate of pollutants, *Estuaries, Hydrocarbons, *Oil industry, Estuarine environment, *Great Britain.

Southampton Water, which is a major estuary in Great Britain, receives a variety of industrial discharges, the largest of which is from a petroleum refinery at Fawley. The seawater waste derived from cooling and processing and discharged to the estuary contains some dissolved, dispersed, and particulate adsorbed heavy and floating oils. Laboratory experiments were conducted to investigate the various biological, chemical, and physical processes which would act on these effluents close to the point of discharge. The effects of such processes as biodegradation, evaporation and bubble ejection, and adsorption of hydrocarbons by estuarine sediments on refinery effluent incubated in glass containers were investigated. The adsorption of petroleum hydrocarbons by estuarine sediments appears to be the most important removal mechanism within the time scale of the estuarine system. In the laboratory studies, 70% of the hydrocarbons originally in the water column were found in the sediments after 1 hour. The initial concentration of the hydrocarbons in the effluent appears to be the rate-determining factor for the adsorption. Compounds of high water solubility were found to be adsorbed to a lesser extent than the less soluble compounds. This rapid near-source sedimentation can be expected to create a deposit of petroleum hydrocarbons which are available for release to the aqueous environment over an extended period. (Carroll-FRC)

Descriptors: *Trace metals, *Bottom sediments, *Phosphorus, *History, Water pollution sources, Copper, Zinc, Lead, Mercury, Magnesium, Chromium, Nickel, *Northern Ireland, Lugh Neagh.

Several studies have reported increases in the flux of certain trace metals to the sediments of aquatic systems in industrial, rural, and remote mountain areas. The concentration-depth behaviors of magnesium, chromium, nickel, copper, zinc, mercury, lead, and phosphorus in three sediment cores from a central site in Lough Neagh, Northern Ireland, were examined for changes in the sedimentary flux of these elements. Lough Neagh is a large, relatively shallow lake with a mainly rural catchment which has become eutrophic due to increases of phosphorus loading. Two main periods of change were found. Widespread and comprehensive woodland clearance in the 17th century resulted in a change in the catchment erosion-leaching regime which produced increased sedimentary magnesium, copper, and lead concentrations. A second and more significant change occurred after about 1880 A.D. The concentrations of chromium, copper, zinc, mercury, lead, phosphorus and, to a lesser degree, nickel were found to increase toward the sediment surface. Differing phosphorus and trace metal profiles, a comparison of the estimated anthropogenic sedimentary flux with background atmospheric conditions, and a general comparison with other situations all suggest that background

atmospheric sources make a substantial contribution to more recent contamination of the sediment with copper, zinc, mercury, and lead. These results indicate that the anthropogenic component of the sedimentary flux of chromium, nickel, copper, zinc, mercury, lead, and phosphorus is important in this rural environmental setting and that the trace-metal contamination of Lough Neagh is part of a global pattern. HUMIC SUBSTANCES,
J. Josephson.
Environmental Science and Technology, Vol 16, No 1, p 20A, 24A, January, 1982. 1 Fig.

Descriptors: *Decomposing organic matter, Water pollution, *CHemical reaction, *Biochemistry, Humic acids, *Fate of pollutants, Chemical analysis, Model studies.

Increasing attention is being focussed on the chemistry and biochemistry of humic substances as a result of their known and perceived threats to safe water. Humic substances, which are formed when living matter dies and decays, react with metals, anions, organics, and chlorine, forming compounds which present health and environmental hazards. The Symposium on Terrestrial and Aquatic Humic Materials, held at Chapel Hill, North Carolina in November, 1981, was convened to exchange ideas and information on the structure, composition, identification, quantification, and control of humic substances and their reaction products. Humic substances absorb and increase the environmental distribution of inorganic and organic micropollutants. Since humic substances are composed of the reaction products of a large number of other compounds, their molecular structures are generaly hard to identify. Examination of their breakdown prducts may provide some clues to their structures. Comparison of the properties of natural humic material with those model synthetic polymers made from likely precursors might also provide insights into their structures. Studies using calcium as a model for reactions were used to examine the removal of humic subtances from solution in natural waters and the treatment of water supplies. Very little information is currently available on the effects of the binding which occurs between humic substances and free metal ions, anions, and/or other radical and molecular groups with which humic substances could react or on the effects of the breakdown of these compounds, although research in this area is beginning. Descriptors: *Sediment transport, *Nuclear wastes, Americium-241, Marine sediments, Plutonium, Water pollution sources, *Radioactive wastes, *Ravenglass Estuary, *Great Britain.

The Ravenglass estuary is of radioecological interest, as it is a site of sediment accumulation close to the Windscale nuclear fuel reprocessing facility. Results are presented of analyses of americium-241 in four cores collected from the Newbiggin area at Ravenglass. Surface segments ranged in Am-241 activity from 48.8 to 60.0 pCi/g. In all four cores, greater Am-241 activities were found at depth and in the buried sediments. Greatest activities were found at a few centimeters depth in the sediments. The occurrence of Am-241 peak activities at lesser depths than predicted in the sediments has been interpreted as resulting from a finite lag-time of transport from Windscale to the estuary. The best estimate of this lag time is about 2.5 years.

SULPHUR IN THE ENVIRONMENT: A REVIEW,
Central Electricity Generating Board, Leatherhead (England). Central Electricity Research Labs.
K. A. Brown.
Environmental Pollution, Series B, Vol 3, No 1, p 47-80, 1982. 1 Fig, 5 Tab, 124 Ref.

Descriptors: *Sulfur, *Environmental effects, Sulfates, Sedimentation, Nutrients, Cycling nutrients, Marine sediments, Reviews, Sulfur cycle, Soil chemistry, Sulfides, Lakes, Lake sediments, Geochemistry, *Path of pollutants.

The path of sulfur compounds released into the atmosphere by man and by natural processes is reviewed, along with their transformation in the atmosphere and deposition to the earth's surface. The size and nature of the sources and sinks of sulfur in soils are discussed in relation to bio- and geochemical processes which govern the soil sulfur cycle, in particular organic matter transformations and mechanisms of sulfur oxidation and reduction. Environmental effects of sulfur pollution in soils and freshwater systems are considered, and the sulfur budget for a freshwater lake is discussed. Sulfur turnover in a freshwater system is compared with that of the marine environment. In fresh waters, most problems arising through sulfur pollution are caused by sulfate reduction to highly toxic sulfide, or by cations associated with sulfate, the direct toxicity of the sulfate anion being extremely low. Eutrophication does not occur as a result of sulfur pollution because sulfate is probably never growth limiting in natural waters. Sulfate can change the path of carbon mineralization in anaerobic sediments by inhibiting methanogenesis, although the significance in nature of this observation is not known. Sulfate reduction in marine sediments may be a major pathway of carbon mineralization. Most of the iron sulfides present in reduced marine sediments have arisen through bacterial sulfate reduction, rather than from degradation of organic matter. (Baker-FRC)

ELIMINATION OF HEXACHLOROBENZENE (HCB) BY RAINBOW TROUT (SALMO GAIRDNERI), AND AN EXAMINATION OF ITS KINETICS IN LAKE ONTARIO SALMONIDS,
Canada Centre for Inland Waters, Burlington (Ontario).
A. J. Niimi, and C. Y. Cho.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 11, p 1350-1356, November, 1981. 4 Fig, 1 Tab, 36 Ref.

Descriptors: *Benzenes, *Chlorine, *Trout, *Lakes, Pollutants, Water pollution, Fish, Kinetics, Mathematical equations, *Industrial wastes, Lake Ontario, *Hexachlorobenzene, Pesticides.

The extensive use and worldwide distribution of hexachlorobenzene (HCB), which is an industrial chemical frequently found in wastewaters, have led to increased concern about its becoming an important environmental contaminant. The rate of elimination of HCB by rainbow trout was established and then related to earlier studies that examined HCB uptake from food and HCB levels surveyed in salmonids from Lake Ontario. Subadult rainbow trout (Salmo gairdneri) were fed diets containing HCB to establish mean body burdens of 225 and 440 micrograms HCB per fish. The rate of elimination was then estimated by sampling conducted after 0, 24, 55, and 110 days. Results of these tests showed that the biological half-life of HCB for these trout was at least 7 months, and perhaps as long as several years. The implications of increasing body weight for kinetics measurements are discussed, and an equation is presented which can be used to adjust for changes in body weight where estimates of half-lives are calculated using tissue concentrations. Use of this information in examining the kinetics of HCB in salmonids collected from Lake Ontario resulted in good agreement between the expected level and that monitored in field samples of rainbow trout, but only fair agreement for lake trout and coho salmon. Differences in the HCB kinetics of these species may be attributed to body weight, age, and perhaps feeding habits. Field sampling programs have resulted in reports of HCB concentrations ranging from 1 to 100 micrograms per kilogram in fish. These levels are probably due primarily to the limited availability of HCB in the Lake Ontario environment. (Carroll-FRC)

GROUND-WATER HYDROLOGY AROUND SALT DOMES IN THE EAST TEXAS BASIN: A PRACTICAL APPROACH TO THE CONTAMINANT TRANSPORT PROBLEM,
Texas Univ. at Austin. Bureau of Economic Geology.
G. E. Fogg, and C. W. Kreitler.
Bulletin of the Association of Engineering Geologists, Vol 18, No 4, p 387-411, 1981. 15 Fig, 1 Tab, 44 Ref.

Descriptors: *Groundwater pollution, *Geohydrology, *Salt domes, Aquifer systems, Waste disposal, Aquitards, Groundwater recharge, Groundwater movement, Radioactive waste disposal, *Texas.

Salt domes in the East Texas Basin are being studied as potential sites for deep burial of nuclear waste. This paper presents a report on progress being made in a program designed to characterize the capability of each of two domes, Oakwood and Keechi, and surrounding media to isolate radioactive wastes. The program includes study of factors which control vulnerability of a dome repository to failure, such as dome growth, cap rock development, and salt dissolution, and of factors which determine how radionuclides would be transported away from a dome should a failure occur. Waste escaping from either dome would, at worst, move into either the Wilcox-Carrizo, a thick, semiconfined, fresh-to-brackish groundwater system, or into the Woodbine Formation, a deeper, saline aquifer. The potential for upward discharge from the Woodbine to the Wilcox-Carrizo appears to be nonexistent at present. Potential impacts of a nuclide escape from the domes into the Wilcox-Carrizo would depend in large part on how deeply recharge over each dome would move contaminants downward and on whether the contaminants would then migrate toward discharge areas in the basin due to topographic effects. Orientation of a moderately brackish-water plume extending away from the Oakwood dome implies topographic control on flow and suggests that contaminants escaping from the dome would become significantly diluted within 5 or 6 miles along the pathway. Groundwater chemistry indicates a trend toward greater capacity for attenuation of radionuclides as fluids move from recharge areas into more alkaline, reducing environments in the artesian sections of the Wilcox-Carrizo. By late 1978 officials of the Environmental Protection Agency had detected more than 12 chlorinated organic compounds in wells serving individuals living near the Hardeman County, Tennessee, toxic waste dump. The most abundant toxic substance detected was carbon tetrachloride. Sixty-one individuals in 16 households used water from wells containing carbon tetrachloride in concentrations exceeding 150 micrograms/liter. Two health evaluations were made. Fifty-nine of the 61 individuals participated in at least one of the two studies; 31 participated in both. Others examined included individuals with less contaminated wells and individuals who had been occupationally exposed to pesticides, including those who had worked at the dump site. The study conducted included a health questionnaire, a clinical examination, and a biochemical screening, with analysis of serum for liver and kidney function parameters, determination of hepatitis A and B serology, and bile acid determinations on fasting and postprandial serum and urine specimens. Initial hepatic profile testing revealed elevated concentrations of the serum enzymes, alkaline phosphatatase and serum glutamic oxaloacetic transaminase in residents using contaminated water. During follow up examinations two months later, these values had dropped significantly, as had postprandial serum concentrations of the bile acids of cholyglycine. The findings suggest a transitory liver injury probably related to exposure to the contaminated drinking water. (Baker-FRC)

INFLUENCE OF WATER MOVEMENTS AND OTHER FACTORS ON DISTRIBUTION AND TRANSPORT OF HEAVY METALS IN A SHALLOW BAY (CANADA),
Alberta Environmental Centre, Vegreville.
J. W. Moore.
Archives of Environmental Contamination and Toxicology, Vol 10, No 6, p 715-724, December, 1981. 5 Fig, 2 Tab, 20 Ref.

Descriptors: *Heavy metals, *Bays, Water pollution, Bottom sediments, Cyanide, Arsenic, *Mine wastes, Lead, Copper, Zinc, Mercury, Iron, *Canada, *Path of pollutants, Great Slave Lake, *Yellowknife Bay.

Yellowknife Bay, which is situated on the north slope of Great Slave Lake in northern Canada, receives a continuous discharge of liquid mine wastes, including heavy metals, salts, and cyanide, from an operating gold mine. The concentrations of heavy metals in the water and sediments of the bay were measured and correlated with water movement, water depth, distance from the waste source, and the organic content of the sediments. Arsenic reached a maximum concentration of 3100 milligrams per kilogram in sediments near the waste source, decreasing to less than 12 milligrams per kilogram in the extreme reaches of the bay. The corresponding ranges for other heavy metals were 13 to 800 milligrams of lead per kilogram, 45 to 785 milligrams of copper per kilogram, 23 to 935 milligrams of zinc per kilogram, 35 to 505 micrograms of mercury per kilogram, and 1.9% to 6.3% iron. Although most pollutants were recorded at low levels in the water, arsenic and copper rose to 0.75 and 0.29 milligrams per liter, respectively, coincident with maximum discharge from the mine. The most important factor governing the distribution of metals in the bay was found to be water movement, generated by inflowing rivers and wind. While surrounding islands also restricted the movement of pollutants through the bay, water depth, slope of the bottom and organic content of the substrate did not appear to have a significant impact on the concentrations of heavy metals in the sediments. (Carroll-FRC)

AN EVALUATION SYSTEM TO RATE FEEDLOT POLLUTION POTENTIAL,
Science and Education Administration, Morris, MN. North Central Soil Conservation Research Lab.
R. A. Young, M. A. Otterby, and A. Roos.
Agricultural Reviews and Manuals ARM-NC-17, April 1982. 82 p, 3 Fig, 3 Tab, 48 Ref, 6 Append.

Descriptors: *Feedlot runoff, *Animal wastes, *Water pollution sources, *Computer models, Feedlot wastes, Water pollution control, Groundwater pollution, Minnesota, Chemical oxygen demand, Phosphorus, Forecasting, Pollution potential.

An evaluation system was developed through the cooperation of several State and Federal agencies to provide a uniform and objective method of evaluating and rating the pollution potential of the approximately 90,000 animal feedlot operations in Minnesota. The first part of the evaluation consists of five simple questions which can be answered by the feedlot operator, allowing the person making the evaluation to disregard the feedlot immediately if it is definitely not a pollution hazard. If the screening procedure indicates a potential hazard, then a more detailed evaluation form must be completed. The first step is to study the animal lot and the area around it to determine the local watershed, and then sketch the watershed. The next step is to determine the design rainfall for which the feedlot is to be determined. For this model, chemical oxygen demand and phosphorus were selected to represent the potential pollution hazard. The soil cover complex method is used to estimate runoff from rainfall for each area included in the local watershed. Equivalent animal units (EAU) are determined from tables and used as a unit of measure to compare differences in the production of waste constituents by different animal species. Other factors considered in this model include: animal unit density; concentration of runoff at feedlot edge; contact time; pollutant reduction from filtration; and concentration reduction from dilution. Once the final concentration of the runoff at the discharge point is estimated, the pollution hazard can be developed. (Moore-SRC)

RESULTS OF DEEP-WELL INJECTION TESTING AT MULBERRY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
J. J. Hickey, and W. E. Wilson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-193004, Price codes: A02 in paper copy, A01 in microfiche.
Geological Survey Water-Resources Investigations 81-75, 1982. 15 p, 7 Fig, 5 Ref.

Descriptors: *Injection wells, *Industrial wastes, *Transmissivity, *Aquifer characteristics, Geohydrology, *Liquid wastes, Carbonate rocks, Aquitards, Leakage, Groundwater barriers, *Florida, Mulberry, Waste disposal.

At the Kaiser Aluminum and Chemical Corporation plant, Mulberry, Fla., high-chloride, acidic liquid wastes are injected into a dolomite section at depths below about 4,000 feet below land surface. In 1975, a satellite monitor well was drilled 2,291 feet from the injection well and a series of three injection tests were performed. Duration of the tests ranged from 240 to 10,020 minutes and injection rates ranged from 110 to 230 gallons per minute. Based on an evaluation of factors that affect hydraulic response, water-level data suitable for interpretation of hydraulic characteristics of the injection zone were identified to occur from 200 to 1,000 minutes during the 10,020-minute test. Transmissivity of the injection zone was computed to be within the range from 700 to 1,000 feet squared per day and storage coefficient of the injection zone was computed to be within the range from .00001 to .00005. The confining bed accepting most of the leakage appears to be the underlying bed. Also, it appears that the overlying beds are probably relatively impermeable and significantly retard the vertical movement of neutralized waste effluent. (USGS)

A WIND-POWERED, GROUND WATER MONITORING INSTALLATION AT A RADIOACTIVE WASTE MANAGEMENT SITE IN IDAHO,
Geological Survey, Idaho Falls, ID. Water Resources Div.
J. C. Bagby, G. E. Ghering, R. G. Jensen, and J. T. Barraclough.
Geological Survey Water Resources Investigations Open-File Report 81-493, April 1981. 28 p, 14 Fig, 1 Tab, 2 Ref.

Descriptors: *Radioactive waste disposal, *Groundwater, *Monitoring, *Water quality, Path of pollutants, Geohydrology, Waste storage, Water pollution sources, Aquifers, Wells, Contamination, Pumping, Water level, Water sampling, Data collections, *Idaho, Snake River Plain, *Idaho National Engineering Laboratory.

In 1971, four wells were drilled just outside a radioactive solid waste storage and disposal facility located on the Idaho National Engineering Laboratory in southeastern Idaho. This facility, the Radioactive Waste Management Complex (RWMC), has been in use since 1952. These wells serve several purposes: to study the geology and hydrology at the RWMC, to determine the potential for radioactive waste migration, and to obtain water samples to determine if waste products are migrating downward into the Snake River Plain aquifer. Special efforts are made to insure that surface contamination does not enter the wells by either water, wind, or contaminated equipment. A submersible pump and a continuous water-level measuring device were installed in each well. Permanent installation of this equipment allowed the well heads to be sealed while providing for collection of data from these wells. The water-level measuring device is a small diameter, differential-pressure, transducer probe. The transducer produces a variable-reluctance signal which is converted to an analog signal and recorded as the depth to water on a strip chart recorder. Windmill-charged storage batteries provide power for the water-level measuring system. This system is reliable, sensitive, and relatively maintenance free. (USGS)

ASSESSMENT OF WATER QUALITY IN STREAMS DRAINING COAL-PRODUCING AREAS IN OHIO,
Geological Survey, Columbus, OH. Water Resources Div.
C. L. Pfaff, D. R. Helsel, D. P. Johnson, and C. G. Angelo.
Geological Survey Water Resources Investigations Open-File Report 81-409, October 1981. 98 p, 17 Fig, 7 Tab, 43 Ref, Append.

Descriptors: *Water quality, *Streams, *Acid mine drainage, *Water pollution sources, *Data collections, Mine wastes, Strip mines, Geohydrology, Statistical analysis, Sampling, Chemical analysis, *Ohio, Coal mines.

Water quality in the coal-producing areas of eastern Ohio was studied in a two-phase investigation between May 1975 and August 1976. Results of

phase one, a reconnaissance of water quality at 150 sites, indicated that acid mine drainage generally occurred where abandoned drift or strip mines were located, whereas areas characterized by reclaimed or active strip mines showed few instances of acid drainage. Phase two was a detailed study of four small basins: One contained abandoned drift mines; the second, abandoned strip mines; the third, reclaimed strip mines; the last, active strip mines. Results of phase two were similar to those of phase one. (USGS)

SULFUR BACTERIAL PROBLEMS REVISTED,
S. Smith.
Water Well Journal, Vol 36, No 2, p 45-46, 1982. 7 Ref.

Descriptors: *Bacteria, *Sulfur, *Corrosion, *Hydrogen sulfide, Water quality, Water analysis, Chemical analysis, Well water, Wells, *Water pollution sources.

There are two very distinct forms of bacteria which interact with sulfur compounds to cause water problems. First there are sulfur or sulfide oxidizers, which are aerobic and require oxygen for growth. The second group are the sulfate-reducers (SRB), which generate hydrogen sulfide and are implicated in the corrosion of iron and steel as well as concrete and other materials subject to attack by hydrogen sulfide. Sulfur bacteria live and act as part of a very complex system of interacting soil chemistry and bacteria. They are the primary agents responsible for the cycling of sulfur compounds through the biosphere, although inorganic processes do remove the bulk of the mineral sulfur through simpler cycles involving sulfide minerals. Sulfur bacteria are found in almost every imaginable environmental condition. Detection and treatment of sulfur bacteria infestations are considered. The simplest and most reliable means of detection is microscopic examination, providing that enough material is present. Treatment for sulfate reducing bacteria is fairly routine. All sulfur bacteria are killed by chlorination. SRBs are also controlled by aeration, since oxygen is poisonous to them. Use of chlorinated drilling water and the avoidance of introducing soil into the borehole are helpful. During routine bacterial tests for coliform types, laboratory tests should also be run to determine iron and sulfur bacteria. (Baker-FRC)

THE DISSIPATION OF NONYLPHENOL IN STREAM AND POND WATER UNDER SIMULATED FIELD CONDITIONS,
Forest Pest Management Inst., Sault Ste. Marie (Ontario).
K. M. S. Sundaram, and S. Szeto.
Journal of Environmental Science and Health, Part B, Vol 16, No 6, p 746-776, 1981. 4 Fig, 10 Ref.

Descriptors: *Microbial degradation, *Organic compounds, Streams, Ponds, Biodegradation, Sediments, Sedimentation, Nonylphenol, *Fate of pollutants, Aquatic environment, Northland Creek, Hargraft Lake, *Ontario, Canada.

The behavior of nonlyphenol was investigated in a static aquatic environment. Natural waters and pond sediment were taken from Northland Creek and Hargraft Lake, northeast of Sault Ste. Marie, Ontario, Canada. Nonylphenol was rapidly dissipated from both stream and pond water when incubated in open flasks at 16 degrees C under simulated field conditions in the environmental chamber. The concentrations decreased exponentially. Nonylphenol persisted much longer in both stream and pond water when incubated in flasks closed with polyethylene snap caps under identical environmental conditions. A transformed product was detected in both stream and pond water when incubated in closed flasks for more than 3 days. The transformed product is probably more polar than the parent, since its retention time was shorter than that nonylphenol in reverse-phase solvent elution, Its formation may be due to photooxidation or microbial hydroxylation of nonylphenol in the aquatic system. The presence of sediment greatly reduced the loss of nonylphenol from pond water through surface volatilization and codistillation. Most of the nonlyphenol adsorbed onto the particulate matter in suspension and then gradually settled in the sediment. Less than 5% of the added nonlyphenol was still present in water incubation for 4 days, and nonlyphenol was no longer detected in water after 10 days. Nonylphenol persisted in autoclaved sediment, but disappeared rapidly in ono-autoclaved sediment. These findings suggest that nonlyphenol was rapidly lost in natural sediment due to microbial degradation. (Baker-FRC)

RETENTION OF URBAN DERIVED PHOSPHORUS BY AN ALLUVIAL SWAMP OF THE COASTAL PLAIN OF GEORGIA,
Georgia Southwestern Coll., Americus. Dept. of Biology.
W. L. Tietjen, and J. C. Carter.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224635, Price codes: A05 in paper copy, A01 in microfiche. Report ERC 05-81, July 1981. 68 p, 2 Fig, 17 Tab, 21 Ref. 2 Append. OWRT A-084-GA(1).

Descriptors: *Phosphorus, *Alluvial deposits, *Swamps, *Retention time, Retention capacity, Urban runoff, Urban drainage, Wastewater, Phosphorus removal, Alluvial rivers, Streams, Detention time, Settling basins, *Nutrient removal, Wastewater facilities, Wastewater treatment, Effluent streams, Effluents, Enrichment, Muckalee Creek, *Georgia, Coastal plains, Urban sewage effluent.

The alluvial swamp system of Muckalee Creek near Americus, Georgia was studied for the entire year of 1979 to determine its capability for retaining phosphorus (P) derived from sewage treatment plant effluent and other urban sources. Retention was determined by comparing the swamp P influx (enrichment) from the urban sources, with P outflux five kilometers further downstream. The annual P aqueous concentration in water above the enrichment point was 0.05 mg P/liter, while that below this point was 0.17 mg P/liter. The annual mean estimates for P movement rates were 0.52, 0.84, 0.45, 1.44, and 0.37 g P/second for input sewage, unknown urban sources, upstream contribution, stream transport out of the swamp, and total retention within the swamp, respectively. Only about 20% of the incoming P was retained by the swamp, with an estimated 6.11 g P/ sq m/year. The P accumulation rate in soil sediments is unknown, but it appears that the swamp soil is the major sink for swamp P retention. The data suggest that the contention that the swamp is important in retaining urban-derived P is sound. (Zielinski-MAXIMA)

ACID PRECIPITATION IN THE WASHINGTON CASCADES,
Central Washington Univ., Ellensburg. Dept. of Chemistry.
L. C. Duncan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224643, Price codes: A02 in paper copy, A01 in microfiche. Report, September 1981. 20 p, 5 Fig, 5 Tab, 22 Ref. OWRT A-110-WASH(1), 14-34-0001-1151.

Descriptors: *Acid rain, *Hydrogen ion concentration, *Water analysis, *Sulfuric acid, *Air pollution effects, Rainfall, Air pollution, Fallout, Acidic water, Acidity, Sulfates, Seasonal variation, Watersheds, Catchment areas, Rainfall impact, Local precipitation, Water quality, Pollutants, Ecological effects, Environmental effects, *Washington Cascades, Water pollution sources.

Five sites maintained across the Washington Cascades from January-June 1981 sampled precipitation for determinations of its potential acidity. The precipitation collected at each site was acidic in that the average pH values were substantially below pH 5.6, a level expected for waters containing only equilibrium concentrations of dissolved carbon dioxide. The pH values varied somewhat with lcoation. Sulfate was the dominant negative ion at all sites, even after correction for sea-salt input. The mean strong acid composition over the sites ranged 50-57 weight-% H2S04. Precipitation falling on the Cascades east and windward of the urban Puget Sound area was notably acidic, with a volume average pH of 4.71 at the Cascade Crest (Snoqualmie Pass). Strong acid content in precipitation increased in the summer months. In addition, 29 watershed source lakes lying along the Cascade Crest 3-20 miles north of the site collectors were sampled in the summer of 1981; all lakes were found to be highly sensitive (but not acidified), with alkalinities ranging from 4-190 microequivalents/liter (mean value of 50.4). The lakes were nonetheless, considered to be highly susceptible to acid input, being in a region of thin top soil and resistant strata. (Zielinski-MAXIMA)

NONPOINT SOURCE POLLUTION FROM AGRICULTURAL WATERSHEDS ON COASTAL PLAIN SOILS,
Delaware Univ., Newark. Dept. of Agricultural Engineering.
W. F. Ritter.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224650, Price codes: A03 in paper copy, A01 in microfiche. Report, April 1981. 31 p, 4 Fig, 17 Tab, 12 Ref. OWRT A-046-DEL(1), 14-34-0001-9008.

Descriptors: *Nonpoint pollution sources, *Agricultural watersheds, *Nitrogen, *Phosphorus, Water analysis, Pollution load, Watersheds, Chemical oxygen demand, Waste load, Organic loading, Nitrogen compounds, Nitrates, Ammonia, Water quality, Model studies, Watershed models, Rainfall, Base flow, Storm runoff, *Delaware, *Coastal plains.

A study was conducted on two rural agricultural watersheds in southern Delaware to obtain information on nitrogen (N) and phosphorus (P) loading rates, and to develop data for future water quality modeling efforts. The amount of rainfall N and P was found to be greater than the nonpoint source N and P loading rates. Over 50% of the N, P, and chemical oxygen demand (COD) loads occurred in baseflow. A larger relative percentage of total P, COD, and organic N was transported during storm runoff than nitrate-N. However, there was no observed relationship between N and P concentrations and flowrate for either watershed. Installing best management practices would not greatly affect the reduction of N and P loads. The two watersheds were monitored for a two-year period, with storm runoff, baseflow samples, and rainfall analyzed for nitrate-N, ammonia, organic N, orthophosphorus, total P, COD, and pH. In 1979, the total N and P loading rates were 24.7 and 1.3 kg/ha for one watershed, and 20.8 and 1.4 kg/ha for the other. (Zielinski-MAXIMA)

METAL CONCENTRATIONS IN GUAM URBAN RUNOFF,
Guam Univ., Agana. Water and Energy Research Inst.
W. J. Zolan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224775, Price codes: A03 in paper copy, A01 in microfiche. Technical Report No 25, June 1981. 27 p, 5 Fig, 8 Tab, 19 Ref, 2 Append. OWRT A-011-GUAM, 14-34-0001-9012.

Descriptors: *Urban runoff, *Heavy metals, *Water analysis, *Water pollution sources, *Water quality standards, *Guam, Runoff, Urban drainage, Urban areas, Mercury, Lead, Cadmium, Hydrogen ion concentration, Hardness, Contamination, Water pollution, Water quality, Recharge basins, Watersheds, Watershed management, Groundwater basins.

Northern Guam serves as a recharge watershed for the groundwater aquifer that supplies most of Guam's drinking water. Samples from five sites in northern Guam which best characterize runoff from commercial and residential areas were analyzed for heavy metals to assess the potential for aquifer contamination. The 13 metals investigated were arsenic, barium, cadmium, chromium, copper, iron, lead, manganese, mercury, nickel, selenium, silver, and zinc. Analyses revealed low levels (in the microgram/liter range) of these metals. Mercury, lead, and cadmium approached/exceeded drinking water standards as dissolved metals in urban runoff. Chromium, copper, iron, manganese, nickel, and zinc were below drinking water standards, but approached/exceeded surface water standards. Other metals analyzed were very low. Suspended metal concentrations were generally higher than dissolved metal concentrations. Metal concentrations in commercial runoffs far exceeded those in residential runoffs. However, commercial runoff waters are discharged in a manner that does not pose a threat to groundwaters used for drinking water. It was concluded that the metal levels found were generally lower than observed in other U.S. communities. Other data (such as pH, total solids, hardness) indicate that urban runoff quality has not changed in the past four years. Further study is needed to determine the distribution of metals in Guam's environment. (Zielinski-MAXIMA)

SEPTIC LEACHATE SURVEYS FOR LAKESIDE SEWER NEEDS EVALUATION,
K-V Associates, Inc., Falmouth, MA.
W. B. Kerfoot, and S. M. Skinner, Jr.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1717-1725, December 1981. 6 Fig, 4 Tab, 13 Ref.

Descriptors: *Septic wastewater, *Water pollution sources, *Leachates, Septic tanks, Lakes, Sewer systems, *Lake shores, Groundwater, *Crystal Lake, *Michigan.

A review of wastewater facilities planning for rural lake communities showed that facility plan proposals often viewed the existence of shoreline septic facilities as a priori evidence of water quality problems, that only casual efforts were made to determine whether any cause-and-effect relationships existed between individual septic systems and perceived water quality problems, and that public health officials were generally unprepared to provide comprehensive information on actual water quality and the effect on public health from shoreline septic systems. A specially designed survey was conducted along the shoreline of Crystal Lake in northern Michigan to demonstrate a method for increasing the effectiveness of evaluation of septic systems. The performance of shoreline on-lot treatment systems was analyzed through the use of a newly developed septic leachate detector, a groundwater flow meter, a surface and groundwater sampling program, and mathematical techniques for evaluating the condition of groundwater plumes. Three different types of discharges from malfunctioning shoreline systems were identified by the survey: erupting groundwater plumes, dormant (seasonal) groundwater plumes, and surface-water plumes. The position and density of plumes were related to the observed flow of shoreline groundwater. The survey showed that more than 90 groundwater plumes of wastewater origin were entering the shoreline from the 1090 seasonal and year-round residences. The greatest frequency of erupting plumes was found along the unsewered shoreline. A high correlation was found between the location of emergence of plumes and attached plant growth, particularly Cladophora. There did not appear to be any significant change in surface water nutrient contents as a result of plume emergence. The location and characteristics of emergent plumes were directly related to the prevailing groundwater flow. (Carroll-FRC)

HYDRODYNAMIC DISPERSION DURING ABSORPTION IN A FINE SAND 1. THE CONSTANT CONCENTRATION CASE,
New South Wales Univ., Kensington (Australia). School of Civil Engineering.
K. K. Watson, and M. J. Jones.
Water Resources Research, Vol 18, No 1, p 91-100, February, 1982. 8 Fig, 14 Ref.

Descriptors: *Solute transport, *Absorption, *Dispersion coefficient, Numerical analysis, Sand, Hydrodynamics, Unsaturated flow, Soil water, Path of pollutants.

This paper reports results of the investigation of the velocity dependence of the hydrodynamic dispersion coefficient for a fine sand during horizontal adsorption of a solute under constant concentration conditions. Experimental data obtained with Bungendore fine sand was compared with quasian-alytical solutions using constant-valued dispersion coefficients and with numerical solutions. Agreement was good when a constant dispersion coefficient of 10 to the minus 8th power sq m per sec was used. Results from computer-based numerical analysis agreed well with the integral solution. Concentration profiles obtained from numerical analysis in the case of a velocity-dependent dispersion coefficient had less scatter than experimental data. Therefore, the velocity-dependent effect cannot be described solely on the basis of experimental data. The fact that the Peclet numbers appropriate to the system were greater than unity suggests that the dispersion coefficient is velocity dependent and that the parameters used in the numerical analysis to express this dependence are satisfactory for Bungendore fine sand under constant concentration absorption. SURFACE CHEMICAL THEORY AS AN AID TO PREDICT THE DISTRIBUTION AND THE FATE OF TRACE CONSTITUENTS AND POLLUTANTS IN THE AQUATIC ENVIRONMENT,
Eidgenoessische Technische Hochschule, Zurich (Switzerland).
W. Stumm.
Water Science and Technology, Vol 14, No 1/2, p 481-491, 1982. 6 Fig, 1 Tab, 21 Ref.

Descriptors: *Adsorption, *Particulate matter, *Sedimentation, *Fate of pollutants, Surface chemistry, Mass transfer, Model studies.

Surface chemical theory provides some of the information (constants and coefficients related to adsorption and mass transfer) needed to describe the reactions occurring at the water-particulate interface and to predict the fate of pollutants in the aquatic environment. The emphasis of the discussion is adsorption of dissolved species onto aquatic particles and the role of scavenging by settling particles. Models for predicting adsorption and settling are reviewed. IMPACT OF DISCHARGES AS A BASIS FOR CONTROL MEASURES,
Union Carbide Corp., South Charleston, WV.
R. A. Conway.
Water Science and Technology, Vol 14, No 1/2, p 95-109, 1982. 4 Fig, 4 Tab, 25 Ref.

Descriptors: *Risks, *Water quality standards, *Environmental effects, Fate of pollutants, Solute transport, Chemical reactions, Biotransformation, Ecological effects, Water pollution effects, Decision making, Model studies, Effluent standards, Data collections, Chemical wastes, Wastewater pollution, *Water pollution control.

Methods of environmental risk analysis are described as a basis for tailoring water pollution control measures to individual effluents and receiving waters. There are 4 basic approaches to environmental risk analysis. The stochastic-statistical approach establishes correlations between input of a material and results. The model ecosystem, or microcosm, tests the results of a pollutant on a physical model of an environmental situation, for example, an aquarium. The deterministic approach uses mathematical models to describe the fate and transport of pollutants in the environment. The baseline approach constructs full-scale characterizations of transport, persistence, and effects of chemicals and compares results of later pollutant additions with the original data. Tiered testing protocols start with simple screening tests to guide decision making for materials of small impact and use tests of increasing complexity as decisions having large impact are needed. Tables list some candidate tests for screening the ecological impact of new products and effluents, mechanisms affecting environmental fate of chemicals, and environmental process and properties (physical, chemical, and biological transformations and transports). Mathematical models for estimating concentrations of chemicals after transport and transformation are reviewed. (Cassar-FRC)

A SURVEY OF AZINPHOS METHYL AND AZINPHOS METHYL OXON IN WATER AND BLUEBERRY SAMPLES FROM HANCOCK AND WASHINGTON COUNTIES OF MAINE,
Maine Univ. at Orono. Dept. of Food Science.
R. J. Bushway, W. Litten, K. Porter, and J. Wertam.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 3, p 341-347, March, 1982. 1 Fig, 3 Tab, 6 Ref.

Descriptors: *Insecticides, *Fate of pollutants, *Pesticides, Azinphos methyl, Guthion, *Maine, *Blueberries, Well water, Water pollution, Streams.

Water samples at seven sites in Washington and Hancock Counties, Maine, were analyzed for the insecticide azinphos methyl (guthion) and its metabolite, azinphos methyl oxon. The pesticide is sprayed extensively on low bush blueberry acreage. Azinphos methyl was detected in two locations: household well water in a sprayed field, 1900-24,000 ng per liter; and process water from a blueberry processing plant, 12,700 ng per liter. No azinphos methyl oxon was detected in any sample (detection limit, 230 ng per liter). The other five sites with nondetectable levels of azinphos methyl were two streams, a pond outlet, a clam flat area, and a tidal flat. The well water sample was analyzed several times during the summer, during which the pesticide was applied twice. The high concentration of 24,000 ng per liter was found on

July 23. The August 11 sampling showed no detectable pesticide. Most likely this reduction was caused by groundwater dilution rather than degradation. (Cassar-FRC)

RADIOTRACER EXPERIMENTS ON PHOSPHORUS UPTAKE AND RELEASE BY LIMNETIC MICROZOOPLANKTON,
Canada Centre for Inland Waters, Burlington (Ontario).
W. D. Taylor, and D. R. S. Lean.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 11, p 1316-1321, November, 1981. 8 Fig, 2 Tab, 15 Ref.

Descriptors: *Phosphorus, *Lakes, *Microorganisms, Zooplankton, Phosphorus radioisotopes, Nutrients, Phosphate, Isotopic tracers, Metabolism, Path of pollutants, *Phosphorus uptake and release, Strombidium virde, *Ontario, Canada.

Previous studies have suggested that very small zooplankton, particularly ciliated protozoa, might be particularly important in mineralization of limnetic phosphorus. This study investigated phosphorus uptake and release by Strombidium viride, a ciliate species abundant in lake plankton. Addition of carrier-free 32P04 to lakewater resulted in gradual labeling of S. viride over at least 30 hours. The label entered the protozoa primarily by the ingestion of labeled particles 0.2 to 1.0 microns in size; direct uptake of phosphate or uptake of particles 5 microns or larger was relatively slight or absent. S. viride transferred to unlabeled lake water lost 32P by a discontinuous process, presumed to be defecation, and by a relatively slow continuous process. The latter process was presumed to be the equivalent of what is usually termed excretion for crustacean zooplankton and is equivalent to a turnover time for the animal's phosphorus content of many hours. Release experiments with the rotifer Keratella cochlearis resulted in similar total losses of 32P, although defecation provided a much larger portion of the total. The turnover times for excretion were similar for the two organisms. Analysis by gel filtration showed that the soluble phosphorus released by both species was primarily phosphate. The results of these experiments do not support the conventional view that microzooplankton regenerate dissolved phosphorus much more rapidly for their biomass than do larger crustacean zooplankton. GROUNDWATER STRATEGY: PROTECTING A VITAL RESOURCE,
C. W. Warren.
Clearwaters, Vol 11, No 1, p 6-7, March, 1981.

Descriptors: *Groundwater, *Water resources development, *Aquifers, Contamination, Water pollution sources, *Legislation, Legal aspects, Regulations, Standards, *Water pollution control, United States.

Groundwater is seriously contaminated in many areas throughout the nation. This contamination includes a variety of materials such as toxic organic and inorganic chemicals. No federal health standards exist for most of the organic chemicals found in drinking water. There are two major sources of groundwater contamination: hazardous waste dump sites and wastewater surface impoundments. Over 600 cases of groundwater contamination due to impoundments have been reported in the nation. Even this number is probably a very low estimate of actual cases. Recent national monitoring efforts have confirmed that groundwater contamination is widespread. Frequently contaminants are found at high concentrations, due to the fact that aquifers do not provide the natural dilution which occurs in surface waters. A contaminant that penetrates groundwater tends to form a plume of highly contaminated water which moves very slowly. Clean-up of contaminated aquifers is an extremely expensive and difficult process. The most inportant laws which deal with groundwater contamination are the Federal Water Pollution Control Act, the Safe Drinking Water Act, the Toxic Substances Control Act, the Resource Conservation and Recovery Act, and the recently passed 'Superfund' legislation. The EPA is now proposing a National Groundwater Protection Strategy which should help focus on the goal of protecting the groundwater resources. (Baker-FRC)

EFFECT OF TURBULENT DISPERSION ON THE RATE OF AMMONIA NITROGEN IN RIVERS,
Technical Univ. of Istanbul (Turkey). Environmental Sciences Div.
D. Orhon, and E. Goneng.
Water Science and Technology, Vol 14, No 1/2, p 345-366, 1982. 20 Fig, 2 Tab, 9 Ref.

Descriptors: *Ammonia, *Turbulent flow, *Nitrification, *Fate of pollutants, Rivers, Chemical reactions, Oxidation, Biochemical oxygen demand, Shock loads, Plug flow, Industrial wastes, Fertilizers, Model studies, *Turkey, Porsuk River.

A model for predicting the fate of ammonia in rivers subject to unsteady discharges includes biochemical oxidation and longitudinal dipsersion components. Theoretical analysis and field tests on the Porsuk River determined that the concept of turbulent diffusion should be included in the model to prevent the misleading conclusions obtained when rivers are idealized as plug flow reactors. This river receives periodic loads of ammonia from a fertilizer factory. The effect of turbulent diffusion is less important at high rates of biochemical conversion. (Cassar-FRC)

ENVIRONMENTAL IMPACT OF THE MICROBIAL AEROSOL EMISSIONS FROM WASTEWATER TREATMENT PLANTS,
Metropolitan Sanitary District of Greater Chicago, IL.
C. Lue-Hing, D. R. Zenz, and S. J. Sedita.
Water Science and Technology, Vol 14, No 1/2, p 289-309, 1982. 9 Fig, 5 Tab, 20 Ref.

Descriptors: *Wastewater treatment, *Risks, *Public health, *Microorganisms, *Chicago, Illinois, Viruses, Bacteria, Aerosols, Coliforms, Aeration, Air pollution, Water pollution effects, Fate of pollutants, *Environmental effects.

Microbial aerosol emissions from wastewater treatment plants are not a significant health risk to the population living in the vicinity of a treatment plant. This is the conclusion of a literature survey and analysis of data collected at a plant operated by the Metropolitan Sanitary District of Greater Chicago in 1979-80. Aerosol sampling in vertical profiles above the aeration tanks and 5, 25, and 50 m downwind of the aeration tanks showed that standard plate count levels of bacteria declined exponentially with distance above the tanks and linearly with distance downwind of tanks. At a distance of 50 m downwind, the fecal coliforms and total coliforms approached background levels. Net bacterial emissions (background subtracted) measured 0.3 m above 2 tanks were 0-1136 colony forming units per cu m, with geometric means of 386 and 208 cfu per cu m above each tank. No detectable animal viruses were collected 3 m downwind of the aeration tanks. (Cassar-FRC)

Descriptors: *Suspended solids, *Effluents, Sedimentation, *Sediments, Water pollution sources, Wastewater treatment, Biological treatment, Biological wastewater treatment, *Path of pollutants, *Radioactive traces, Tracking techniques.

This study was undertaken to identify and quantify the major pathways through which effluent total suspended solids are assimilated naturally in receiving waters. Effluent suspended solids were traced in a receiving stream by using a radioisotope tag. The findings suggest that the major sink for total suspended solids discharged from biological treatment systems is oxidation, while the solids remain in suspension. Effluent biosolids also were ingested and incorporated into the cellular materials of aquatic food-chain organisms in a logical food-chain pattern. The C-14 tagged biosolids discharged to the receiving water traced the effluent solids at a diluted TSS concentration of 2 mg/l. Sediment traps placed in pools behind dams captured less than 5% of the discharged solids. Over 95% of the discharged solids remained suspended or were oxidized in the stream, even though stream velocities were conducive to settling. All measureable C-14 contained in the effluent from a 1-day aerated stabilization basin was incorporated in solids that were suspended. A 31% reduction in C-14 tagged biosolids occurred during 2.5 days of plug-flow travel through an unaerated polishing pond following aerated stabilization basin (ASB) treatment. Of the amount removed in the polishing pond, 36% settled, and it was postulated that the remaining 64% exited as methane or carbon dioxide. Additional treatment consisting of aeration and quiescent detention for 0.25 day resulted in a 6% reduction in TSS. Of that amount, 48% was traced to sediment and 52% to having escaped as methane or carbon dioxide. (Baker-FRC)

MANGANESE, ZINC AND COPPER IN HYDROBIONTS IN THE DANUBE AND THE NORTHWESTERN BLACK SEA,
Institute of Biology of the Southern Seas.
L. I. Rozhanskaya, and O. B. Spirandi.
Hydrobiological Journal, Vol 17, No 1, p 78-83, 1981. 1 Tab, 19 Ref.

Descriptors: *Heavy metals, *Aquatic life, *Path of pollutants, Manganese, Zinc, Copper, *Black Sea, *Danube River, Rivers, Fish, Algae, Mollusks, Metabolism, Aquatic plants.

The concentration of heavy metals by hydrobionts in the Danube and the adjacent Northwestern Black Sea was investigated. Phyllophora collected in July 1977 in the Northwestern Black Sea had a very high manganese content of 740 mg/kg wet mass. The amount of manganese in Phyllophora obtained in the same area in August was 151 mg/kg. The amount of manganese in Cystoseira was 14.0 mg/kg. The concentration of manganese in Cystoseira barbata collected in the Black Sea was considerably lower, between 1.7 and 2.4 mg/kg wet mass. Zinc content in Phyllophora was higher

LIBRARY U. OF L. URBANA-CHAMPAIGN

than in the other algal species, but one order lower than manganese. The amount of zinc in Phyllophora was 70.3 mg/kg in July and 26.3 mg/kg in August. The amount of zinc in Enteromorpha collected in the Black Sea along the Rumanian coast was 107 mg/kg. High zinc content was noted in the viscera of fish, especially bream, in which the content was 2920 mg/kg ash, or 70.2 mg/kg wet mass. The highest copper content was recorded in the July Phyllophora samples at 29.4 mg/kg. The high content of all trace elements in the July Phyllophora was probably connected with its growth. Almost all the young segments developing in the spring reach maturity in July. The concentration factors determined here in hydrobionts from the Danube and the Northwestern Black Sea may be used when setting standards for the pollution of water by heavy metals. (Baker-FRC)

CHEMICAL CHANGES OF LAKES WITHIN THE MOUNT ST. HELENS BLAST ZONE,
Washington Univ., Seattle. Fisheries Research Inst.
R. C. Wissmar, A. H. Devol, A. E. Nevissi, and J. R. Sedell.
Science, Vol 216, No 4542, p 175-178, April 9, 1982. 2 Fig, 1 Tab, 19 Footnotes.

Descriptors: *Lakes, *Volcanoes, *Water quality, Dissolved solids, Mount St. Helens, Washington, Air pollution, Fate of pollutants, Chemical composition.

Water in 12 lakes devastated by the Mount St. Helens May 18, 1980, eruption and in 4 lakes outside the blast zone were sampled on June 30, 1980. Changes in dissolved constituents depended on the lake's location relative to the lateral blast trajectory of the eruption and to the location of mineral deposits. In general Spirit Lake showed the greatest changes. Total alkalinity increased 22-fold; Mn, 815-fold; Fe, 193-fold; phosphate, 248-fold; sulfate, 157-fold; and chloride, 85-fold. K, Na, Ca, Mg, P, silicate, ammonia, Al, and Cu were enriched to a lesser degree, 13 to 40-fold. Zn, Pb, and Sb were increased from 2 to 4-fold. Enrichments of dissolved chemicals in other lakes also reflect the influences of dissolution of magmatic and lithic deposits. pH changes were minor because of buffering by carbonic acid, neutralization by mineral particles, the limited acid sulfate alteration of minerals, and dissociation of dissolved humic substances. (Cassar-FRC)

RADIONUCLIDES IN MONO LAKE, CALIFORNIA,
Lamont-Doherty Geological Observatory, Palisades, NY.
H. J. Simpson, R. M. Trier, J. R. Toggweiler, G. Mathieu, and B. L. Deck.
Science, Vol 216, No 4545, p 512-514, April 30, 1982. 2 Tab, 16 Ref.

Descriptors: *Fate of pollutants, *Radioisotopes, *Lake sediments, *Water pollution sources, Radioactive wastes, Adsorption, Uranium radioisotopes, Isotope studies, Radium radioisotopes, Plutonium, Thorium, Carbonates.

In the water column of Mono Lake, a natural alkaline, saline lake of California, unusually high levels of uranium (U), thorium (Th) and plutonium (Pu) have been recorded. Information on the behavior of radionuclides in natural waters may aid in assessment procedures for the isolation and storage of nuclear wastes. The enhanced solubility of actinide elements with oxidation states IV to VI was attributed to complexing with carbonate ions. After inorganic carbon was experimentally removed from lake water by acification, and the pH was adjusted to 10, over 90% of the Th and Pu moved from the aqueous to the sediment phase, while the particle concentration of U increased. Fallout strontium-90 has been largely removed from the water, most probably as a result of coprecipitation with calcium carbonate. Daughter/parent activity ratios of Th, radium, and U isotopes indicate that Th is removed from the water column on time scales much longer than a month and that the desorption of Th from sediments to the water column takes place in less than a few years. (Geiger-FRC)

THE IMPACT OF FISH FARMING ON WATER QUALITY,
Solway River Purification Board (Scotland).
D. J. Tervet.
Water Pollution Control, Vol 80, No 5, p 571-581, 1981. 7 Fig, 6 Tab, 16 Ref.

Descriptors: *Fish farming, *Water quality, Water use, Water pollution control, Diseases, Public health, Fish diseases, Wastewater, Fish food, Pollutants, Water pollution sources.

The dramatic increase in the fish farming industry has caused river authorities to become concerned about the pollution potential of this industry. Water quality problems resulting from fish farming include abstraction problems, pollution control problems, and disease control problems. Pollution control, which is particularly important when high densities of fish are being maintained with water of restricted availability, is caused primarily by wasted food and fecal material. In order to investigate the pollution control problems related to fish farming, a brief survey of general conditions at fish farms within the Solway River Purification Board's area in Scotland was conducted, and one particular rainbow trout rearing farm was studied in detail in order to quantify the pollution problems. These studies showed that a considerable reduction of water quality occurred on many occasions at fish farms and that these occasions were especially serious where the farms abstracted most of the water flow from a watercourse. The extent of the reduction in water quality was found to correlate closely with the weight of fish carried and the flow through a farm. It was concluded that pollution was liable to result downstream from fish farms unless annual production rates were maintained at levels well below 200 tons for each 1 cubic meter per second of available flow. This constraint is less important as the residual flow in the watercourse increases, but is significantly affected by the quality of water available. It may be necessary to install effluent treatment processes at fish farms in order to maintain current production rates. (Carroll-FRC)

GROUNDWATER POLLUTION INVESTIGATIONS IN THE GREAT OUSE BASIN,
Anglian Water Authority (England).
D. J. Tester, and R. J. Harker.
Water Pollution Control, Vol 80, No 5, p 614-631, 1981. 4 Fig, 6 Tab, 25 Ref.

Descriptors: *Water pollution sources, *Groundwater pollution, *Waste pollution prevention, *Water quality control, Aquifers, Leachates, Solid waste disposal, Oil spills, Great Ouse Basin, England.

The principal aquifer of the Great Ouse basin is the Chalk, which supplies over 50% of the water needs of East Anglia. Waste disposal, effluent discharges, and accidental spillage were investigated at several sites in the basin where the groundwater in the underlying aquifer was thought to be contaminated by chemical spillage, waste disposal activities, and agricultural practices. The investigations were designed to establish the extent of contamination of the aquifer in the vicinity of the site, to assess the pollution risk to abstractors and/or surface watercourses resulting from the spread of pollutants from the site and to determine any necessary remedial actions, and to provide more information on the movement and attenuation of pollutants in groudwater. The results of two case studies which provided useful information on the movement and attenuation of pollutants in the Chalk aquifer are presented. Chloride was found to be an effective tracer of sewage effluent contamination. Organic matter was found to rapidly attenuate within short distances of sewage disposal sites. The potential use of the Chalk aquifer for sewage treatment is discussed. Biological activity affects groundwater quality by depleting dissolved oxygen levels and using oxygen chemically bound to nitrate and/or sulfate. Traces of certain soluble complex organic compounds present in oil spills can persist in the aquifer and can seriously affect the quality of the groundwater. (Carroll-FRC)

THE OCCURRENCE OF SEWAGE-BORNE PATHOGENS IN THE UK,
Liverpool School of Tropical Medicine (England). Dept. of Parasitology.
W. Crewe, and R. R. Owen.
Water Pollution Control, Vol 80, No 5, p 632, 637, 1981. 4 Fig, 1 Tab.

Descriptors: *Pathogens, *Municipal wastewater, *Parasites, Public health, Protozoa, Trematodes, Nematodes, Cestodes, Great Britain, Water pollution sources.

A considerable number of protozoan and helminth parasites could theoretically be transmitted through sewage in the United Kingdom. The transmission of fecal-borne human parasites of humans usually depends upon human ingestion of the state of the parasite which is found in sewage following contamination of food or drink. Parasites transmitted in this way include the intestinal protozoa Entamoeba histolytica, the cause of amoebic dysentery, and Giardia intestinalis, which often causes severe diarrhea. The only trematode parasite of humans found in the United Kingdom is the sheep liver fluke, which could only be transmitted if sewage containing the eggs of the parasite were spread on pasture on which the right species of snail was breeding. Although the eggs and larvae of some common intestinal nematodes are found in considerable numbers in sewage sludges in Great Britain, they cannot be transmitted because suitable conditions for their development in soil are not common there. The nematodes Ascaris and Trichuris are transmitted, at least in small numbers, through sewage sludges used as garden fertilizers. The beef tapeworm is the only parasite of humans indigenous to the United Kingdom which is cause for concern. This parasite, which is of veterinary and economic importance, is found in sewage in the stage infective to cattle. Further information is needed before any conclusions can be drawn concerning the importance of sewage sludge in the spread of pathogens generally, and parasites specifically. (Carroll-FRC)

THE FATE OF ORGANIC POLLUTANTS IN FROZEN WATERS: SUNLIGHT PHOTODECOMPOSITION OF URACIL HERBICIDES IN FROZEN AQUEOUS SOLUTIONS,
Utah Water Research Lab., Logan.
A. J. Acher.
Water Research, Vol 16, No 4, p 405-410, April, 1982. 3 Fig, 2 Tab, 12 Ref.

Descriptors: *Decomposition, *Fate of pollutants, *Herbicides, *Pesticide kinetics, *Ice cover, Degradation, Hydrogen ion concentration, Pesticides, Oxidation, Irradiation, Organic pesticides, Organic compounds.

The photooxidative stability of two uracil herbicide derivatives in frozen sensitized solutions under simulated winter conditions was examined. Solutions of bromacil and terbacil were exposed directly to sunlight or covered by different thicknesses of ice. At all three pH levels tested (6.8, 8.2, and 9.1), both herbicides were rapidly decomposed by sunlight in the presence of a sensitizer, methylene blue, rose bengal or riboflavin. In the first two hours of irradiation, the maximum decomposition of bromacil and terbacil occurred in the alkaline pH range when the sensitizers were used. At pH 6.8, a practical rate of photodecomposition was found only for terbacil. When the frozen samples were covered by 11 cm of ice, the photodecomposition rates remained high enough to be of practical value. Extract residues of irradiated solutions of bromacil and terbacil contained no herbicides upon TLC and GC-MS analysis. Only small amounts of one decomposition product were found in a residue concentrate of the bromacil solution, while minute quantities of four decomposition products

were found in a residue concentrate of the terbacil solution. (Geiger-FRC)

BIODEGRADATION OF SYNTHETIC CRUDE OIL IN TWO RIVERS OF NORTHERN ALBERTA, CANADA,
Department of Fisheries and Oceans, Winnipeg (Manitoba). Freshwater Inst.
M. A. Lock, R. R. Wallace, and D. W. S. Westlake.
Water Research, Vol 16, No 4, p 497-500, April, 1982. 1 Fig, 1 Tab, 16 Ref.

Descriptors: *Fate of pollutants, *Biodegradation, *Oil, *Aquatic bacteria, Microbial degradation, Water temperature, Rivers, Oil pollution, Hydrocarbons, Water pollution sources.

The potential capacity of the Muskeg and Steepbank, two brown-water rivers in Northern Alberta, to biodegrade synthetic crude oil was examined in laboratory tests. The Steepbank River flows through the Athabasca oil sand deposits characteristic of this area. Samples of water and rocks were taken from various stations in December 1977 and were exposed for various periods of time to previously frozen and sterilized water samples from either river. Gas chromatographs from these incubates were compared with incubates containing known oil-degrading bacteria cultures. All samples of water and epilithon from both rivers were able to biodegrade the saturate fraction of synthetic crude oil resulting from the up-grading of oil sand suggesting that the oil degradative capability of river microorganisms was ubiquitous in this area. At 4 degrees, degradation was quite rapid, although even higher degradation rates were observed at 20 degrees. The Muskeg and Steepbank water temperatures are close to 0 degrees for about six months of the year. (Geiger-FRC)

FILTERING OF DISSOLVED OXYGEN DATA IN STREAM WATER QUALITY ANALYSIS,
Hawaii Univ., Honolulu. Dept. of Civil Engineering.
C. C. K. Liu.
Water Resources Bulletin, Vol 18, No 1, p 15-20, February, 1982. 5 Fig, 1 Tab, 11 Ref.

Descriptors: *Dissolved oxygen, *Water quality, *Streams, Simulation analysis, Data interpretation, Decomposing organic matter, Mathematical models.

Most of the stream biological oxygen demand/dissolved oxygen water quality models currently used for the purpose of waste assimilative capacity analysis and waste load allocation in natural receiving waters are steady state models, largely due to their simplicity. In a bioligically active stream, observed dissolved oxygen content is the result of several dynamic processes, including photosynthesis and respiration actions which cause diurnal fluctuations of oxygen levels. A set of equations has been developed which can be used to separate the time varying effects of these biological activities from observed dissolved oxygen data based only on readily available field data. The resultant steady state dissolved oxygen profile allows a reasonable stream simulation based on a model and data which do not contain dissolved oxygen due to biological activities. By excluding the highly variable processes of biological dissolved oxygen production and consumption, this method significantly simplifies stream dissolved oxygen modelling. Unless changes in stream ecology are a major concern, it is desirable to formulate the stream water quality model without this time-varying term. (Carroll-FRC)

NITRATE REDUCTION BY PSEUDOMONAS SPP.: ANTAGONISM BY FERMENTATIVE BACTERIA,
Freshwater Biological Association, Ambleside (England).
R. W. Horsley, J. V. Roscoe, and I. B. Talling.
Journal of Applied Bacteriology, Vol 52, No 1, p 57-66, 1982. 3 Fig, 4 Tab, 32 Ref.

Descriptors: *Bacteria, *Nitrates, *Denitrification, Fate of pollutants, Nitrites, Heterotrophic bacteria, Rivers, Escherichia coli, Aeromonas hydrophila, Enterobacter aerogenes, Chemical reduction, Oxidation-reduction potential.

Pseudomonas denitrificans was incubated aerobically or anaerobically with fermentative heterotrophs (Aeromonas hydrophila, Escherichia coli, and Enterobacter aerogenes) at ratios of 100:1 to 0:100 in culture media comprised of glycerol, yeast extract, and 140 or 700 mg per liter nitrate-N. Under aerobic and anaerobic condition and with a 140 mg per liter nitrate-N concentration, 97-99% of nitrate was reduced at all ratios of A. hydrophila and E. coli with P. denitrificans. Nitrite accumulated only in the presence of pure heterotroph cultures. At the 700 mg per liter concentration of nitrate-N, 12-100% of the nitrate was reduced to nitrite in mixed cultures of P. denitrificans:heterotroph at ratios of 10:1 or less. P. denitrificans and A. hydrophila mixtures produced less nitrite than did coliforms. Inhibition of nitrate reduction was evident when 100-150 mg per liter nitrite-N had accumulated in the media. As nitrite accumulated in the 700 mg per liter nitrate-N culture, P. denitrificans decreased in number and heterotrophs slightly increased. When P. denitrificans, E. coli, and 50:50 mixtures of the two bacteria were added to autoclaved river water containing 3.5-10.0 mg per liter nitrate-N and 0.23-0.81 mg per liter nitrite-N, nitrite concentrations after incubation for 7 days at 20 C were (in mg per liter) E. coli, 1.48-5.03; P. denitrificans, 0.05-0.48; and 50:50 mixture, 0.06-1.12. TRANSPORT PROCESSES OF COPPER AND ZINC IN A HIGHLY EUTROPHIC AND MEROMICTIC LAKE,
Eidgenoessische Anstalt fuer Wasservorgung, Abwasserreinigung und Gewaesserschutz, Kastienbaum (Switzerland). Lake Research Lab.
P. Baccini, and T. Joller.
Schweizerische Zeitschrift fur Hydrologie, Vol 43, No 1, p 176-199, 1981. 18 Fig, 3 Tab, 19 Ref.

Descriptors: *Copper, *Zinc, *Lakes, Sedimentation, Eutrophic lakes, Meromictic lakes, Sedimentation rates, Heavy metals, Iron, Anaerobic conditions, Diffusion coefficient, Mathematical models.

Previous studies of the effects of heavy metal inputs on the ecology of aquatic systems have indicated that copper and zinc are the two elements whose tolerance limits should be lowered to prevent toxic effects on plankton communities in Swiss running waters. The residence time of copper and zinc in holomictic systems under aerobic conditions can be predicted if the production of biomass, the sedimentation rate, and the hydraulic properties of the lake are known. Lake Baldegg, a meromictic lake in central Switzerland, was selected for study of the effects of a permanent anaerobic hypolimnion on the transport of copper and zinc within the lake. An analysis of the seasonal variations of the dissolved and particulate concentrations of the two metals indicated that a significant quantity of particulate copper is formed in the hypolimnion. Zinc did not show a similar pattern. Analysis of the sedimentation rates at the lake bottom indicated that there is a distinct difference between copper and zinc in a period of high organic production and stagnation. While zinc correlates well with organic carbon, copper does not. Zinc was found to be more strongly assimilated into planktonic particles than was copper, with most of the particulate zinc reaching the sediment being of autochthonous origin. Copper, but not zinc, was also sorbed on iron particles formed in the upper hypolimnion at the Fe(3+)/Fe(2+) interface, leading to additional copper elimination by sedimentation. A flux scheme for the hypolimnic transport of copper, which was quantified in a one-dimensional diffusion model, was used to explain the observed variations of concentration profiles. (Carroll-FRC)

ELEVATED CONCENTRATIONS OF ACTINIDES IN MONO LAKE,
Woods Hole Oceanographic Institution, MA. Dept. of Chemistry.
R. F. Anderson, M. P. Bacon, and P. G. Brewer.
Science, Vol 216, No 4545, p 514-516, April 30, 1982. 2 Tab, 25 Ref.

Descriptors: *Radioisotopes, *Fate of pollutants, *Radioactive wastes, *Saline lakes, Thorium, Uranium radioisotopes, Plutonium, Protactinium, Lakes, Water pollution sources, Carbonates.

Tetravalent thorium (Th), pentavalent protactinium (Pa), hexavalent uranium (U), and plutonium (Pu) are present at higher concentrations in Mono Lake water than in seawater. Low ratios of actinium to Pa and americium to Pu suggested that the levels of trivalent actinides in the water column are not similarly enchanced. High levels of the ordinarily insoluble actinides are kept in solution by natural ligands such as carbonate ions or alkaline brines. This effect inhibits their chemical removal from the water column and has important implications for the management of radioactive wastes and their transport in groundwater. (Geiger-FRC)

A COMPUTER MODEL FOR HEAVY METAL TRANSPORT WITHIN THE PENOBSCOT RIVER,
Maine Univ. at Orono. Dept. of Civil Engineering.
J. H. Fitch, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236589, Price codes: A05 in paper copy, A01 in microfiche. M.S. Thesis, May, 1979. 79 p, 1 Fig, 3 Tab, 23 Ref, 5 Append. OWRT A-037-ME(2).

Descriptors: *Heavy metals, *Mathematical models, *River flow, *Pollution load, *Water pollution, Pollutant identification, Computer models, Model studies, Computers, Mathematical studies, Mixing, Zones, Reach, River mechanics, Flow, Streamflow, River wash, Adsorption.

A three-component integrated mathematical model was developed and computerized for use in predicting heavy metal concentrations (dissolved and fixed) at locations downstream from a waste discharge to a river. The model was formulated using a step-wise approach which first simulates the mixing of a waste steam with a river flow, then simulates adsorption-desorption reactions, and finally simulates particulate transport. Mixing and adsorption-desorption reactions are assumed to occur in a mixing zone at the beginning of each river reach. The mixing zone output is considered to be stable with respect to metal speciation throughout the reach, and is used as input data to the particulate transport model to determine metal locations at any reach point. Use of the modified Einstein procedure afforded a description of particulate motion in the river. It was concluded that: river sediment motion is important for describing river heavy metal movement; interactions of ions, particulates, and other natural substances must be described to simulate heavy metal transfer within natural waters. In addition to predicting heavy metal concentrations at any given point, location of contamination areas may also be feasible. (Zielinski-MAXIMA)

Report No 107, August, 1981. 213 p, 81 Fig, 35 Tab, 39 Ref, 7 Append. OWRT B-137-COLO(1), OWRT B-170-COLO(5).

Descriptors: *Nonpoint pollution sources, *Sediment transport, *Simulation analysis, *Solute transport, *River basins, Pollution load, Sediments, Suspended load, Suspended solids, Sediment discharge, Tractive forces, Sediment-carrying capacity, Channel flow, Channeling, Slope degradation, Rills, Computer models, Model studies, Saltation, Catchment areas.

The role of sediment in diffuse-source salt loading in the upper Colorado River basin was investigated. The results proved that entrainment and transport of sediment by overland and channelized flow are crucial factors affecting the salinity of runoff from diffuse source areas. Increased concentration of transported sediment increases the availability of soluble minerals; further transported sediment may continue dissolving due to kinetic disequilibrium and/or when mixed with Colorado River water. Sediment yield increases during rilling with a contemporaneous increase in solute yield. Rills form faster and are undercut to a greater extent by direct runoff than by rainfall-induced runoff. The importance of rill flow to erosion and solute yield is so overwhelming that a computer simulation of rill pattern and its variation with hillslope inclination was developed. The most practical conclusion arising from the rilling effect is the indirect dependence of solute yield on hillslope inclination. Regression of solute yield on hillslope inclination. Regression of solute yield versus slope may be used as a reliable procedure to estimate solute yield under varying climatic conditions from diffuse source areas that are comparable in terms of their soluble mineral concentration and erodibility. Ionic derivatives of more soluble minerals are more common as sediment load increases. Recommendations for decreasing solute yields are provided. (Zielinski-MAXIMA)

THE SOCIO-ENVIRONMENTAL IMPACTS OF ENERGY DEVELOPMENT ON LOCAL USER GROUPS AND WATER RESOURCE PLANNING,
Washington State Univ., Pullman.
R. L. Wisniewski, and W. R. Freudenburg.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236670, Price codes: A07 in paper copy, A01 in microfiche. Report, October, 1981. 114 p, 7 Fig, 38 Tab, 60 Ref, 1 Append. OWRT A-106-WASH(1), 14-34-0001-1151.

Descriptors: *Nuclear powerplants, *Public opinion, *Public utility districts, *Surveys, *Electric power production, Fuel reprocessing, Powerplants, Nuclear reactors, Radioactive wastes, Attitudes, Public participation, Social participation, Construction, Nuclear energy, Environmental effects, Environmental protection, Regional development, Regional analysis, Urban planning.

Assessment was made of the soci-environmental impacts created by the Grays Harbor County twin nuclear power generating plants being constructed by the Washington Public Power Supply System (WPPSS), using a combination of methods. The methods included over 300 interviews concluded in the immediate vicinity of the plants, and another 300 in a comparison area of eastern Pacific County. Five major conclusions were reached: both Counties showed strong opposition to the power plants, and to nuclear power, in general; water quality issues appeared to be a major reason behind the opposition; Grays Harbor County residents appeared significantly more concerned about most sources of pollution than Pacific County residents; residents of the region may have a moderate tendency to underestimate their own contributions to existing water quality problems; and, residents in both counties evidenced relatively little awareness of water conservation possibilities. The results of this study implied that an energy facility builder's action can have significant consequences for local and regional public opinion, which, in turn, can have significant implications for the builder. Public opinion appears to have been strongly affected by a perceived lack of competence on the part of WPPSS and by the perception that WPPSS has failed to devote adequate consideration to local preferences. Public attitudes were not predictable on the basis of economic factors alone. (Aielinski-MAXIMA)

AGRICULTURAL RUNOFF AND WATER POLLUTION,
Department of the Environment, Victoria (British Columbia). Assessment and Planning Div.
J. H. Weins.
Canadian Water Resources Journal, Vol 5, No 3, p 78-89, 1980. 13 Ref.

Descriptors: *Agricultural runoff, *Nonpoint pollution sources, *Animal wastes, British Columbia, Water pollution sources, Agricultural wastes, Legislation, Regulations, Water pollution control, Farm management, Farm wastes, Nutrients, Sediments, Pesticides, Fertilizers, Feedlot runoff.

Livestock activities (dairy farms, beef feedlots, cattle overwintering areas, waste storage areas, and watering locations) are the most serious sources of agricultural runoff pollution to surface and groundwater in British Columbia. These activities raise levels of BOD, fecal coliforms, nitrogen, and phosphorus in watercourses and downstream lakes, especially during spring melt and rainfall events. Other nonpoint source pollutants--sediment, pesticides, and fertilizers--are less of a problem in this region. Several legislative acts regulate pollution from agricultural activities. The Agricultural Environmental Control program, organized in 1975, handles pollution complaints and promotes improvements in farm management practices. Essentially it is a combined regulatory and voluntary system. Some perceive this program as inadequate. Some measures to reduce pollution from agricultural sources include: education and extension programs, monitoring both on a regular basis and during special events (snowmelt, high and low flow), pilot improvement projects to investigate and demonstrate runoff control technologies, and review of present voluntary and regulatory measures. Environmental Pollution, Series B, Vol 3, No 2, p 81-100, February, 1982. 4 Fig, 4 Tab, 44 Ref.

Descriptors: *Rivers, *Nutrients, Cycling nutrients, Orthophosphates, Phosphates, Nitrates, Ammonium, Nitrite, Seasonal variations, Water pollution effects.

This paper discusses the use of river concentration and mass flow data to suggest the possible nature of equilibrium processes which affect river nutrient concentrations. The concurrent analysis of biologically more stable ions was used to obtain some form of internal standardization for the nutrient assessment. The concentrations of orthophosphate, nitrate, ammonium, and nitrite were determined and found to demonstrate significant natural fluctuations dependent upon effects related to season and/or river flow. A mass flow balance suggests appreciable losses of both orthophosphate and ammonium following pollutant inputs. No comparable losses, other than that accountable for by tributary dilution, occurred for nitrate, nitrite or the various biologically stable ions studied concurrently to act as internal standards. COPPER POLLUTION STUDIES IN LAKES GEORGE AND EDWARD, UGANDA: THE DISTRIBUTION OF CU, CD AND FE IN THE WATER AND SEDIMENTS,
East African Freshwater Fisheries Research Organization, Jinja (Uganda).
F. W. B. Bugenyi.
Environmental Pollution, Series B, Vol 3, No 2, p 129-138, February, 1982. 2 Fig, 6 Tab, 10 Ref.

Descriptors: *Water pollution sources, *Lakes, Lake George, Lake Edward, Uganda, Copper, Cadmium, Iron, Sediments, Water quality, Path of pollutants, Lake sediments.

A program was initiated in East African lakes to obtain baseline information on the distribution of copper in the water body, the sediments and the biota and also on its toxic effects on the aquatic biota, particularly the Tilapia fish species, which form a major commercial fishery and food resource for the area. Nine sampling sites were established on the water system: River Nyamwamb-Lake George-Kazinga channel-Lake Edward. The distribution of copper, cadmium, and iron in the entire water system showed no major differences in the concentrations in the surface, mid-depth, and bottom waters. However, a gradual drop was noted in the concentrations in the sediments from Lake George to Lake Edward. The sediments act as natural sinks for a large fraction of the metal ions. The chemical oxygen demand, the ionic conductivity, and the volatile organic carbon results indicate that Lake George has higher COD and lower ionic conductivity values, whereas Lake Edward has higher COD and conductivity values. The indirect effect of this fact on the distribution of the heavy metals was noted. The higher concentrations of phosphates in Lake George ensure an abundance of algal blooms and thus higher turbidity. This leads to lower transparency values. The reverse is true for Lake Edward. Concentrations of copper, iron and cadmium appear likely to cause little environmental damage at the present time. (Baker-FRC)

QUANTITATIVE ASSESSMENT OF FILAMENTOUS ALGAE AS A SOURCE OF DETERIORATING WATER QUALITY IN CANALS,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
O. P. Oksiyuk, F. V. Stol'berg, and V. N. Sotnikov.
Hydrobiological Journal, Vol 16, No 6, p 69-73, 1980. 1 Fig, 1 Tab, 13 Ref.

Descriptors: *Algae, *Biological oxygen demand, *Canals, Water pollution sources, Filamentous algae, Canal linings, N. Donets-Donbass Canal, Water quality, Organic matter, Cladophora, Spirogyra.

Data (962-76) on water discharge, flow rate, filamentous algal biomass, and BOD in the N. Donets-Donbass Canal, USSR, were analyzed to derive a quantitative picture of the role of filamentous algae in water pollution. In lined canals these algae increased BOD by hyperproduction of organic matter. In 1968 algae produced BOD equivalent to 46,000 g oxygen per 100 km of canal length, corresponding to the effluents of a city with 200,000 to 300,000 population. An equation is given to calculate the input of organic matter and increase of BOD in the canal water from cross sectional area, canal length, flow velocity, and canal discharge. Mean annual indices should be used to counteract the variations caused by temperature and life cycles of the algae. (Cassar-FRC)

EFFECT OF SEWAGE EFFLUENT ON THE SEDIMENTS OF NORDASVATNET (A LAND-LOCKED FJORD), NORWAY,

Alexandria Univ. (Egypt). Dept. of Oceanography.
M. K. El-Sayed.
Marine Pollution Bulletin, Vol 13, No 3, p 85-88, 1982. 2 Fig, 2 Tab, 22 Ref.

Descriptors: *Wastewater disposal, *Sediments, *Metals, Fate of pollutants, Water pollution sources, Fjords, Heavy metals, Organic matter, Anaerobic conditions, Iron, Manganese, Copper, Zinc, Bottom sediments, Carbonates.

Sediments from the anoxic Nordasvatnet fjord, Norway, which receives 8000 cu meters per day of untreated domestic sewage, were analyzed. Concentrations of metals and other constituents were: total iron, 2.53-5.75%, average 4.2%; manganese, 300-1400 ppm, average 565 ppm; copper, 20-125 ppm, average 41.2 ppm; zinc, 72-427 ppm, average 209.5 ppm; carbonate, 1.2-12.2%, average 7.6%; and organic carbon, 2.5-12.5%, average 9.97%. Concentrations of heavy metals were highest in the upper layers of the core samples; carbonate levels increased from the srface to the deeper levels. (Cassar-FRC)

AN APPROXIMATE PETROLEUM HYDROCARBON BUDGET FOR THE HUDSON RARITAN ESTUARY--NEW YORK,
State Univ. of New York at Stony Brook. Marine Sciences Research Center.
D. W. Connell.
Marine Pollution Bulletin, Vol 13, No 3, p 89-93, 1982. 1 Fig, 2 Tab, 29 Ref.

Descriptors: *Oil pollution, *Sediments, *Industrial wastes, Oil spills, Path of pollutants, Fate of pollutants, Water pollution sources, Hudson River, Raritan River, Estuaries, New York Bight, New York, Polyaromatic hydrocarbons, Runoff, Wastewater pollution, Dredging, Evaporation, Organic compounds.

A petroleum budget for the Hudson Raritan Estuary, New York, estimated from published literature, accounted for an input of 92 tons per day and losses of 70 tons per day. Inputs (in tons per day) were: sewage discharges, 35; oil refinery discharges, 1.3; non-oil refinery industrial discharges, 17; oil spills, 1.5; atmospheric deposition, 0.002; urban and rural runoff, 37. Losses (in tons per day) were: permanent deposition in sediments, 11; dredging, 5.8; advection, 6.5; bed sedimentary transport, 0.007; decomposition in water and sediments, 42; evaporation, 0.4; movement of surface slicks, 0.4. FECAL COLIFORM DENSITIES IN A WESTERN WATERSHED,
Black and Veatch, Denver, CO.
P. J. Psaris, and D. W. Hendricks.
Water, Air, and Soil Pollution, Vol 17, No 3, p 253-262, 1982. 3 Fig, 2 Tab, 11 Ref.

Descriptors: *Coliforms, *Bacteria, *Irrigation water, Path of pollutants, South Platte River, Colorado, Water quality standards, Wastewater disposal.

Fecal coliforms concentration data (EPA STORET records, 1980) from 99 sampling stations throughout the South Platte River system, Colorado, were analyzed. Coliform densities were 0-99 organisms per 100 ml in mountain streams and 10,000-100,000 organisms per 100 ml or higher in plains streams. The source of coliforms is wastewater discharged by municipalities into the river system or into land disposal areas. Colorado Departmet of Health standards (200 fecal coliforms per 100 ml for Recreation Class I, 1000 for irrigation water, and 2000 for Recreation Class 2 and Drinking Water Supply Class 2) were exceeded by 33-53% of stations overall, depending on use, by 3-12% of mountain stations, and by 50-75% of plains stations. Water from this river system is widely spread during irrigation. The current policies encouraging land treatment and reuse of wastewater should be reviewd with respect to compliance with proposed fecal coliform standards. (Cassar-FRC)

OCCURRENCE AND DISTRIBUTION OF CHEMICAL POLLUTANTS IN LAKE MARIUT, EGYPT, I. RESIDUES OF ORGANOCHLORINE PESTICIDES,
Alexandria Univ. (Egypt). Dept. of Oceanography.
M. A. H. Saad, M. M. A. Elamayem, A. H. El-Sebae, and I. F. Sharaf.
Water, Air, and Soil Pollution, Vol 17, No 3, p 245-252, 1981. 3 Fig, 3 Tab, 18 Ref.

Descriptors: *Fish, *Water analysis, *Pesticides, Fate of pollutants, Saline lakes, Accumulation, Lake Mariut, Egypt, Insecticides, Lakes, DDT, Lindane, Chlorinated hydrocarbons, Pollutant identification.

Water and fish from the brackish coastal Lake Mariut, Egypt, were analyzed for organochlorine pesticides at monthly intervals from August 1978 to July 1979. The lake has been severly polluted by human, industrial, and agricultural wastes. Mean concentrations of several pesticides (in ppb) were: lindane, 2.09; p,p'-DDE, 4.49; o,p'-DDT, 0.01; p,p'-DDT, 0.13; and total DDT, 5.1. DDT levels were highest (about 10 ppb) in January-March with a secondary peak (8 ppb) in October. Lindane levels were highest in October (8 ppb) and lowest in November-February. In Tilapia fish the mean concentrations (in ppb) of pesticides were: lindane, 35.0; p,p'-DDE, 39.0; p,p'-DDT, 17.4; and total DDT, 60.8. Higher pesticide concentrations in the southern part of the lake reflected input of drainage waters. (Cassar-FRC)

DETERMINATION OF RECENT DESPOSITION RATES IN LAKE CONSTANCE WITH RADIOISOTOPIC METHODS,
Heidelberg Univ. (Germany, F. R.). Lab. for Sedimentology.
J. Dominik, A. Mangini, and G. Muller.
Sedimentology, Vol 28, No 5, p 653-677, October, 1981. 10 Fig, 11 Tab, 54 Ref.

Descriptors: *Sedimentation rates, *Radioisotopes, *Lead radioisotopes, *Deposition(Sediments), Lead, Zinc, *Lake Constance, Radioactive dating, Dating, Cesium radioisotopes, Heavy metals, Metals, Fate of pollutants, Lakes, Nutrients, Sedimentology, *Lake sediments.

Sedimentation rates were determined with the Pb-210 method in eight sediment cores from Lake Constance. The rate of deposition in the main basin (Obersee) varies from about O.06 g/sq cm/y in the central part to 0.13 g/sq cm/y in the eastern part of the lake and then increases rapidly towards the Rhine delta. In the central lake area the rate of deposition has been approximately constant since 1900, and dating with the Pb-210 method is in good agreement with sedimentological observations. In the Konstanzer Trichter area, the deposition rate has been increasing since about 1955 as a result of eutrophication and subsequent high carbonate production. Dating with Cs-137 is fairly accurate for sediments deposited at a high rate, but is questionable for slowly accumulating ones. A positive correlation of Pb-210 fluxes and sedimentation rates indicates that Pb-210 flux into sediments follows the distribution pattern of solids. Pb-210 profiles in four sediment cores interpreted in terms of a constant flux model display synchronous fluctuation of the sedimentation rate; however, their relation to long-range particulate input variations remains to be proved. Sedimentation rates determined with the Pb-210 method were used to calculate recent nutrient and heavy metal fluxes. Anthropogenic fluxes of Zn and Pb are in the same range of magnitude as in other polluted areas in Europe and America. (Author abstract)

CONTAMINANT DISPERSION IN OSCILLATORY FLOWS,
Cambridge Univ. (England). Dept. of Applied Mathematics and Theoretical Physics.
R. Smith.
Journal of Fluid Mechanics, Vol 114, p 379-398, 1982. 7 Fig, 19 Ref.

Descriptors: *Contamination, *Flow profile, Oscillatory waves, Waves, Mathematical equations, Model studies, *Estuaries, Estuarine environment, *Path of pollutants.

A substantial time span can occur in which a cloud of a contaminant is contracting after each flow reversal in an oscillatory system if the time scale for cross-sectional mixing is comparable with or larger than the flow period. Thus the apparent longitudinal diffusion coefficient in such systems, including many major tidal waterways, is negative. The contaminant dispersion therefore cannot be modeled by a diffusion equation, since negative diffusivities imply the spontaneous development of infinite concentrations. The manner in which this periodic contracting and expanding can be modeled by a delay diffusion equation is demonstrated, using the bulk velocity, a coordinate displacement and the diffision coefficient at a specific time after discharge. The recent memory is always positive and diffusive in character, so singularities cannot arise. However, when the time after discharge is large, this memory function can be negative due to reversed flow at earlier times. Particular attention is given to estuarine flows, and results are derived for the dependence of the diffusion coefficient on the water depth and on the width of the estuary. (Baker-FRC)

ORGANOCHLORINE RESIDUES IN SUSPENDED SOLIDS COLLECTED FROM THE MOUTHS OF CANADIAN STREAMS FLOWING INTO THE GREAT LAKES 1974-1977,
Ontario Ministry of Agriculture and Food, Guelph. Pesticide Residue Lab.
R. Frank, R. L. Thomas, H. Holdrinet, R. K. McMillan, and H. E. Braun.
Journal of Great Lakes Research, Vol 7, No 4, p 363-381, 1981. 2 Fig, 13 Tab, 13 Ref.

Descriptors: *Suspended solids, *Pollutant identification, Sedimentation, *Organophosphorus pesticides, *Great Lakes, Organic compounds, Pesticides, *Canada, Water pollution sources, Land drainage, Path of pollutants.

A study was conducted to determine whether and how the boundary waters of the Great Lakes are being polluted by land drainage. Between 1974 and 1977, 186 samples of suspended solids were collected from 105 stream mouths out of 176 streams draining the Canadian shoreline of the Great Lakes basin. The widespread use of DDT between 1947 and 1971 was reflected in the presence of DDT and its metabolites in suspended solids of all 105 streams sampled. HEOD was detected in 15 of the 43 suspended solid samples collected, with the highest mean residues occurring in streams draining into Lake Ontario along the southwest shoreline. Endosulfan was present in five of the eleven streams draining into Lake Ontario along the southwestern shoreline. Endrin was noted in 30 Mile Creek at 4 micrograms/kg. No residues of chlordane and HE were detected in 1974 samples. During the study period, about 70% of the total insecticides used by Ontario agriculture were applied in the Lake Erie watershed, 14% each in the Lake Ontario and St. Clair watersheds and 2% in the Lake Huron watershed. No aldrin, endrin mirex, heptachlor or organophosphorus insecticides were detected. (Baker-FRC)

ORGANIC CONTAMINANTS IN THE SUSPENDED SEDIMENTS OF THE NIAGARA RIVER,
Canada Centre for Inland Waters, Burlington (Ontario).
N. D. Warry, and C. H. Chan.
Journal of Great Lakes Research, Vol 7, No 4, p 394-403, 1981. 5 Fig, 4 Tab, 7 Ref.

Descriptors: *Suspended sediments, *Organic chemicals, Pesticides, Great Lakes, *Lake Ontario, *Niagara River, Rivers, Sediment transport, Water pollution sources, DDT, Dieldrin, Lindane, Heptachlor epoxide, Chemical analysis, Organic wastes, *Pollutant identification.

A suspended sediment sampling program was initiated in the lower Niagara River during 1978 to

LIBRARY U. OF I., URBANA-CHAMPAIGN

determine quantitatively the presence of organic contaminant residues in the suspended sediments of the Niagara River. This report covers results obtained from April 26, 1979, through April 22, 1980. The suspended sediments provided a continuing source of PCBs and other pesticide residues to Lake Ontario. The loadings are ranked in decreasing order of concentration as PCB, DDT, mirex, chlordane, methoxychlor and endosulfan. The concentrations of all these residues are quite variable with time, with concentration changes up to a factor of 3 not being unusual within a month. The available evidence suggests that active sources of some contaminants are located along the Niagara River downstream from Grand Island. The 1979 loading of total PCBs to Lake Ontario from the Niagara River is 2.7 times the total PCB loading to the whole lake as calculated for 1968, while DDT and mirex loading from the Niagara River in 1979 are less than the 1968 loadings. The most surprising result is that the loading of mirex to Lake Ontario is continuing in spite of the fact that the primary source, Hooker Chemical, no longer produces the pesticide. Other pesticides sought included lindane, dieldrin, endrin, heptachlor, heptachlor epoxide, and aldrin. Of these, only lindane, dieldrin, and heptachlor epoxide were ever detected. (Baker-FRC)

WATER QUALITY MODELING OF LAKE MICHIGAN AND CONSIDERATION OF THE ANOMALOUS ICE COVER OF 1976-1977,
Environmental Protection Agency, Grosse Ile, MI. Large Lakes Research Station.
P. Rodgers, and D. Salisbury.
Journal of Great Lakes Research, Vol 7, No 4, p 467-480, 1981. 10 Fig, 3 Tab, 43 Ref.

Descriptors: Water quality, *Model studies, Lakes, *Lake Michigan, Great Lakes, *Ice cover, *Phosphorus, Phytoplankton, *Load distribution, *Path of pollutants.

The concurrent effects of a phosphorus load reduction in 1977 and a climatically induced ice cover are examined via a phytoplankton simulation model for their relative importance in affecting an observed phosphorus depletion. The application of ecological models to the Lake Michigan basin was the central focus of this research. A modified version of a deterministic phytoplankton mode, Lake 1 by Thomann, was first calibrated to the 1976 Lake Michigan field data. A dynamic phytoplankton simulation model (MICHI) was developed to investigate the observed field data and to use in forecasting lake responses to various phosphorus loading scenarios. The 1977 data indicated that the southern basin of Lake Michigan lost up to 3 micrograms of phosphorus per liter compared to concentrations observed in 1976. In an attempt to simulate this rapid depletion of phosphorus, MICHI required an implicit representation of suspected effects of an extensive ice cover observed during the winter of 1976-77. This included increasing the net apparent settling rate eight fold during ice cover. A total phosphorus model was used in conjunction with MICHI for forecasting. These forecasts indicate a steady-state total phosphorus concentration of 7 micrograms phosphorus per liter, given the target load recommended by the 1978 Water Quality Agreement. The projected time to obtain 95% of steady-state response to a load change was 7-14 years. (Baker-FRC)

GEOCHEMICAL PATHWAY STUDIES OF HEAVY METALS IN LAKE SEDIMENTS FROM THE SUDBURY-TEMAGAMI AREA, ONTARIO,
McMaster Univ., Hamilton (Ontario). Dept. of Geology.
J. H. Crocket, and A. Kabir.
Journal of Great Lakes Research, Vol 7, No 4, p 455-466, 1981, 4 Fig, 7 Tab, 14 Ref.

Descriptors: *Heavy metals, Water pollution sources, Lakes, Industrial lproduction, Fallout, Lead, Nickel, Palladiu,, Gold, Selenium, Copper, Iridium, Neutrom activation analysis, *Lake sediments, *Path of pollutants, atomic absorption, x-ray fluorescence, Canada (Ontario).

Radiochemical neutron activation, atomic absorption, and x-ray fluorescence were used to determine the concentrations of some heavy metals in lake sediments from the Sudbury-Temagami area. Dredge samples were taken from 23 lakes, usually from the deepest part. The study area contains a major world source of nickel and an important producer of copper and other heavy metal byproducts, including the noble metal group. Major nickel and copper minerals of the Sudbury area are pentlandite, pyrrhotite, and chalcopyrite. Concentration gradients for lead, arsenic, and selenium tend to center about the Sudbury industrial complex and increse toward it. Metal concentration profiles over the top 20 cm of sediment core samples from five lakes show pronounced increases in lead, iridium, gold, arsenic, selenium, copper, nickel, and palladium in the top 5 cm. These data suggest that one of the principal routes for heavy metal loading of lake sediments in the area is atmospheric fallout of particulate material. (Baker-FRC).

PESTICIDES AND PCB IN THE GRAND AND SAUGEEN RIVER BASINS,
Ontario Ministry of Agriculture and Food, Guelph. Pesticide Residue Lab.
R. Frank.
Journal of Great Lakes Research, Vol 7, No 4, p 440-454, 1981. 1 Fig, 12 Tab, 34 Ref.

Descriptors: *Polychlorinated biphenyls, *Pesticides, River basins, Catchment areas, Land use, Rivers, Basins, Suspended solids, Great Lakes, *Non-Point sources, Dieldrin, Chlordane, Atrazine, Simazine, *Agricultural chemicals, DDT, Water pollution sources, Agricultural runoff.

This paper forms part of an overall study into pollutant losses from diffuse sources due to land use activities, adding information on pesticides and PCBs to the information base being established. Attempts were made to integrate crop distribution and pesticide use information in order to develop a better understanding of the dispersal of pesticides in two major river systems. The Grand and Saugeen rivers drain two major basins in the Ontario Province of Canada, and discharges into Lake Erie and Lake Huron respectively pesticides were classified as persistent or non-persistent. Members of both categories appeared in upstream waters; however, only the former appeared at the river mouths. Non-persistent pesticides found in the system occurred at the time of spraying or shortly thereafter in storm runoff waters but not at other times. Persistent pesticides found in the system included those that had been discontinued and those in use throughout the study period. Dieldrin, DDT, chlordane, atrazine, and simazine were identified in water or on suspended solids throughout the year. Atrazine was the most widely used pesticide in the basins, and loadings at the mouth appeared to be 0.6% of that applied. Loadings of chlordane and heptachlor epoxide at the mouth suggest that greater inputs were coming from urban uses. PCB was ubiquitious in the two basins, and losses as measured at the river mouths were on the order of 30-40- and 7-10 kg/year for the Grand River and Saugeen River watersheds, respectively. No residues of mirex were detected in either system. (Baker-FRC)

TRANSPORT OF NITRATE AND GASEOUS DENITRIFICATION IN SOIL COLUMNS DURING LEACHING,
Iowa State Univ., Ames. Dept. of Agricultural Engineering.
R. S. Kanwar, H. P. Johnson, and D. Kirkham.
Journal of Hydrology, Vol 55, No 1/4, p 171-184, 1982. 7 Fig, 2 Tab, 25 Ref.

Descriptors: *Nitrates, *Solute transport, Fate of pollutants, Nitrogen compounds, Denitrification, Fertilizers, Leaching, Soil columns.

Nitrate leaching (considered a first-order reaction) in a soil column of finite length was theoretically analyzed. Transport equations and boundary conditions describing nitrate movement and denitrification in soil were solved for continuous application of nitrate at the soil surface. The relative concentration profiles of nitrate movement were obtained for any time and for known values of the diffusion coefficient and average solute velocity. Laboratory experimental data reported in the literature supported the validity of the model. In field conditions an aquifer with moving water would act as a sink. This model is useful in determining the optimum application of fertilizers to agricultural land in order to avoid nitrogen accumulation in the soil or water contamination. (Cassar-FRC)

METHOXYCHLOR RESIDUES IN TREATED IRRIGATION CANAL WATER IN SOUTHCENTRAL IDAHO,
Idaho Univ., Moscow. Twin Falls Cooperative Extension Service.
R. L. Stoltz, and G. A. Pollock.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 473-476, 1982. 2 Fig, 6 Ref.

Descriptors: *Insecticides, *Canals, *Methoxychlor, Pesticides, Twin Falls, Idaho, Fate of pollutants, Snake River.

Methoxychlor, an insecticide used to control black fly larvae in water bodies, reached peak levels of 1.4 ppb, 0.4% of initial concentration (0.3 ppm), during application to a canal system. The water was treated 12 times during the summer of 1980 at Murtaugh Lake on the Twin Falls canal system, Idaho. Samples for residue analysis were taken 42-45 hours after four of the applications at a distance 75 miles downstream before the canal enters the Snake River. Low levels of methoxychlor (0.14 ppb) were present 70 hours after the August applications. All measured methoxychlor levels were far below the 52 ppb LC50 for rainbow trout. (Cassar-FRC)

INDICATIONS OF GROUND WATER INFLUENCES ON NUTRIENT TRANSPORT THROUGH SCHWATKA LAKE, YUKON TERRITORY,
Department of the Environment, Vancouver (British Columbia). Inland Waters Directorate (Pacific Region).
P. H. Whitfield, B. McNaughton, and W. G. Whitley.
Water Resources Bulletin, Vol 18, No 2, p 197-202, April, 1982. 2 Fig, 1 Tab, 7 Ref.

Descriptors: *Nutrients, *Solute transport, *Infiltration water, Groundwater movement, *Canada, Schwatka Lake, Yukon Territory, Phosphorus, Nitrates, Lakes, Nitrites, Nitrogen, Silicates, Carbon, Inorganic carbon, Organic carbon.

Nutrient budgets were estimated for Schwatka Lake, Yukon Territory, formed by the Whitehorse Rapids Dam, by analyzing water samples collected upstream and downstream of the lake. Exports of nutrients, expressed as % of input, were: total P, 17.0; nitrate and nitrite, 19.8; total N, 5.0; silicate, 1.2; inorganic C, 0.1; and organic C, 10.3. The most likely reason for these differences is groundwater contribtions to the lake. A probable source is the wastewater from the White Horse Copper Mines, and a probable route is via the large deposit of unconsolidated material underlying the reservoir. Other processes not considered influential in this particular case are evaporation from the impoundment, land surface drainage, bank erosion, and channel scouring. (Cassar-FRC)

SELECTING A METHOD FOR ESTIMATING SUBSTANCE LOADINGS,

Department of the Environment, Vancouver (British Columbia). Inland Waters Directorate (Pacific Region).
P. H. Whitfield.
Water Resources Bulletin, Vol 18, No 2, p 203-210, April, 1982. 5 Tab, 6 Ref.

Descriptors: *Path of pollutants, *Solute transport, *Nutrients, *Statistical analysis, Schwatka Lake, *Canada, Yukon Territory, Phosphorus, Nitrates, Nitrites, Nitrogen, Silicates, Inorganic carbon, Organic carbon, Carbon, Lakes.

Four methods for estimating mass transport are evaluated using data on nutrient concentrations of waters flowing into and out of Schwatka Lake, Yukon Territory. The four methods are permutations of arithmetic vs. logarithmic normal distributions and independence vs. dependence on discharge. Method A is based on the assumption that concentration data has a unimodal normal distribution and that concentration is independent of discharge. Method B assumes that the logarithmic transfer of the concentration data is unimodal normal and that concentration is independent of discharge. Method C assumes that concentration is unimodal normal and dependent on discharge. Method D assumes that the logarithm of concentration is normally distributed and dependent on the logarithm of discharge. The most precise mass transport estimates were obtained using Method B. Method A overestimated the loadings. Methods C and D were within plus or minus 5% of Method B results in some cases but were inconsistent. (Cassar-FRC)

Descriptors: *Physicochemical properties, *Water quality, Reviews, *St. Lawrence Estuary, *Canada, Quebec, Dissolved oxygen, Water circulation, Salinity, Metals, Estuaries, Mercury, Fish, Suspended sediments, Water pollution sources.

The physicochemical properties of water in the St. Lawrence Gulf (east of Pointe-des-Monts) and Estuary (Quebec City to Pointe-des-Monts) is reviewed. General water circulation, salinity, bathymetry, and river discharges are depicted. Dissolved oxygen in the gulf varies from 1.8 ml per liter in the deep strata to 8 ml per liter in the surface water layer. The minimum oxygen concentrations are found in a 300-370 m deep area located between the Isle d'Anticosti and Newfoundland. pH of water is 8.0 at the surface and 7.6 in deeper water. Sediment pH is 6.9-8.1. Suspended sediments rarely exceed 1 mg per liter. Metals concentrations are generally low. Concentrations determined in one study were (in micrograms per liter): Zn, 10.2; Ni, 4.6; Cu, 4.5; Mn, 2.5; Pb, 2.3; and Cd, V, Mo, and Co all less than 0.4. Mercury levels in fish varied from 0.76 to 1.85 ppm. (Cassar-FRC)

SNOW CONTAMINATION BY HEAVY METALS AND SULPHUR IN CRACOW AGGLOMERATION (SOUTHERN POLAND),
Academy of Mining and Metallurgy, Kracow (Poland). Inst. of Environmental Protection.
P. K. Zajac, and K. Grodzinska.
Water, Air, and Soil Pollution, Vol 17, No 3, p 269-280, 1982. 5 Fig, 9 Tab, 23 Ref.

Descriptors: *Snow, *Steel industry, *Air pollution, Precipitation, Path of pollutants, Sulfates, Heavy metals, Metals, Acid rain, Sulfur compounds, Cracow, *Poland, Water pollution sources.

Samples of snow were collected on 3 dates in 1977 and 1978 at 27 sites in open and forest stands east of the large steel mill at Cracow, Poland. Concentrations of heavy metals, light metals, and sulfate decreased with increasing distance from the source, but snow acidity increased. There was considerable variation in pollutant concentrations in snow between sites, sample sets, type of forest, and open vs. cleared areas. Average metal concentrations (in mg per liter) were: Cd, 0.29; Pb, 3.1; Zn, 8.7; Fe, 923; Mg, 78; and Ca, 325. The mean sulfate ion concentration was 17.25 mg per liter. Snow pH varied from 10 at the source to 5 at a distance of 25 km. (Cassar-FRC)

GROUND-WATER CONTAMINATION DUE TO VANISHING AND FINITE-SIZE CONTINUOUS SOURCES,
Dames and Moore, Golden, CO.
A. Prakash.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 572-590, April, 1982. 10 Fig, 1 Tab, 27 Ref.

Descriptors: *Groundwater, *Water pollution sources, Contamination, Aquifers, Model studies, Mathematical equations, Leaching.

This paper presents simple analytical models to predict the spatial distribution of steady-state concentrations caused by continuous release of contaminants from a point, line, rectangular, or parallelepiped source in a groundwater environment with one- or two-dimensional uniform flow. This formulation includes the contributions of radioactive decay and soil adsorption, and the solutions can be used to approximate transports through stream-aquifer systems and through confined or unconfined aquifers. The results of the analytical model are compared with those of a finite-element study. The analytical model is simple, requires smaller computer time, and is free from convergence and stability problems associated with some numerical models. It is expected that the methods as presented would provide reasonably accurate results for many field situations. Examples are included to illustrate the effect of source configuration, for example point, line or plane, and the presence or absence of a fully penetrating perennial stream in the flowfield. To validate the model, concentration isopleths are developed for the release of effluents from an ashpond in a two-dimensional stream aquifer system. (Baker-FRC)

OCCURRENCE OF ENDOTOXINS IN GROUNDWATER DURING THE LAND APPLICATION OF WASTEWATER,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
S. M. Goyal, and C. P. Gerba.
Journal of Environmental Science and Health, Part A, Vol 17, No 2, p 187-196, 1982. 2 Tab, 10 Ref.

Descriptors: *Groundwater pollution, *Toxins, *Land application, Wastewater disposal, Endotoxins, Bacteria, Algae, Fate of pollutants.

Algal or bacterial endotoxin concentrations were 0.3 to 480 ng per ml in groundwater from wells 3 to 37 m beneath five sewage land application sites in Texas, Michigan, Arizona, and Massachusetts. Concentrations in wastewater samples were 300-6000 ng per ml. The groundwaters with the highest endotoxin levels were found at the sites with the highest endotoxin levels in the applied sewage effluents. Although endotoxin removal in the soil was 90-99.9%, levels were still higher than in most drinking waters (1.25-12.5 ng per ml). Most groundwaters have low or nondetectable levels of endotoxins. The possibility of using endotoxins as indicators of sewage water infiltration was suggested. (Cassar-FRC)

DILUTION OF MUNICIPAL LANDFILL LEACHATE, FRANKLIN COUNTY, INDIANA,
Ball State Univ., Muncie, IN. Dept. of Natural Resources.
P. J. Sullivan, and W. L. Morgan.
Journal of Environmental Health, Vol 44, No 5, p 253-257, March-April, 1982. 3 Fig, 4 Tab, 10 Ref.

Descriptors: *Leachates, *Landfills, Groundwater, Groundwater pollution, Leaching, *Indiana, Sanitary landfills, Waste dumps, Water quality, Rivers, Surface water.

This study was initiated to identify the possible source for contamination of local water resources in Franklin County, Indiana. In this county the sanitary landfill is located in an abandoned gravel pit and has been placed on a mandated phase-out schedule by the Land Pollution Control Division due to its poor geologic location and the absence of adequate leachate control. Soil textures of the daily cover at the landfill range from a sandy loam to a loam. This results in the rapid infiltration of rainfall. Groundwater monitoring wells were installed at several sites, and soil cores were taken. The Whitewater River was sampled upstream and downstream of the landfill as well. The soil coring data clearly demonstrated the lack of an impervious liner to the landfill. Areas south and east of the landfill will allow the movement of the leachate. The clay materials to the west will also force most groundwater flows away from the landfill to the south and southeast. No apparent change was noted in water quality within the Whitewater River. Only low concentrations of trace metals were found in the surface and groundwaters, perhaps due to the formation of insoluble metal complexes as a consequence of alkaline surface and groundwater. The fact that all the non-metal leachate parameters usually fall well below US EPA criteria may indicate that dilution of leachate is occurring. Iron concentrations slightly exceeded these same criteria. Existing groundwater conditions suggest a high volume and rapid movement of water within the aquifer. (Baker-FRC)

MODELS OF LANDFILL LEACHING: ORGANIC STRENGTH,
Wright-Pierce Architects/Engineers, Portsmouth, NH.
W. A. Straub, and D. R. Lynch.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 251-268, April, 1982. 12 Fig, 2 Tab, 26 Ref.

Descriptors: *Landfills, *Leachates, Model studies, Mathematical equations, Infiltration, Percolation, Wastewater disposal, Sanitary landfill, Groundwater pollution, Waste disposal, Waste dumps.

To estimate groundwater pollution potential, mathematical models of moisture movement and inorganic leachate strength which had been applied using analysis of compacted solid waste as an unsaturated porous medium were extended to describe leachate organic strength, microbial activity and gas production. The roles of aerobic and anaerobic bacteria were simulated using conventional kinetic formulations. Computer simulations were obtained for landfill experiments reported by others, and good agreement with observed behavior was demonstrated. The models proved useful in describing organic leachate strength and landfill stabilization. Specific conclusions indicated that convective removal and anaerobic microbial activity dominate leachate organic strength and landfill stabilization. Convective effects may be dominant in some cases. Aerobic activity is relatively unimportant in determining the long-term quality of leachate when external air is not supplied to the landfill. Anaerobic activity was noted to occur in the landfill at a rate inhibited from ideal rates. The Monod kinetic model is useful in preliminary descriptions of anaerobic activity and indicates inhibition within the landfill. A microbial kinetic model may be useful in estimating landfill gas production. Finally, the retention of cells within the landfill system during recirculation of leachate may be a primary contributor to the accelerated

LIBRARY U. OF I., URBANA-CHAMPAIGN

organic stabilization typical of such systems. (Baker-FRC)

MODELS OF LANDFILL LEACHING: MOISTURE FLOW AND INORGANIC STRENGTH,
Wright-Pierce Architects/Engineers, Portsmouth, NH.
W. A. Straub, and D. R. Lynch.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 231-250, April, 1982. 14 Fig, 33 Ref.

Descriptors: *Leachates, *Model studies, Landfills, Waste disposal, Mathematical studies, Infiltration, Percolation, Waste dumps, Sanitary landfills, Wastewater disposal, Groundwater pollution.

The literature concerning both empirical investigations and modeling of leachate production are reviewed, and models are developed which simulate landfill moisture movement and the inorganic contaminant strength of leachate. The models are used to simulate leachate behavior from experimental landfills documented by other investigators in order to illustrate their analytical potential. The study demonstrated the feasibility of analyzing compacted solid waste as an unsaturated porous medium. The advantage of this analytical approach lies in its process orientation - leachate quantity and quality result from the interaction of fundamental transport phenomena within specific physical and environmental settings. At present, leachate models are appropriate primarily for research purposes, insofar as they provide organized analytical structures for the design and interpretation of experiments. Simulations obtained with preliminary, aggregate representations of major hydraulic and contaminant transport processes are in overall agreement with leachate data documented in separate studies. Additional experimental work is needed identify and refine the description of basic processes occurring in the landfill environment. Ultimately, porous medium-based landfill models could be applied to field scale problems, although it must be noted that such applications would require extensive empirical support. (Baker-FRC)

TOTAL SUSPENDED SOLIDS IN HIGHWAY RUNOFF IN WASHINGTON STATE,
RH2 Engineering, Seattle, WA.
R. Asplund, B. W. Mar, and J. F. Ferguson.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 391-404, April, 1982. 3 Fig, 6 Tab, 37 Ref.

Descriptors: *Suspended solids, *Runoff, Highways, Roads, Rainfall, Rainfall-runoff relationships, Water pollution sources, *Washington.

A characterization of total suspended solids (TSS) found in highway storm water runoff was based on the first year of continuous statewide monitoring at nine sites in the state of Washington. The major topics explored included a comparison of the data collected from this project with previously published data, a determination of trends in the data which may support the development of a model, and a determination of the major sources of storm water runoff TSS and parameters which may influence TSS deposition and removal from the highway. During this year a total of 241 storms were sampled with a composite sampling system. Vehicle traffic during the storm was found to be the principal factor influencing the mass of suspended solids in the runoff. During winter ice conditions a major fraction of solids loadings in runoff could be traced to sand use. A predictive model for total suspended solids loadings was derived as a function of cumulative traffic during the storms. Traffic during the dry periods appeared to remove pollutants from the highway and is not significant in predicting pollutant loadings in the state of Washington. (Baker-FRC)

QUALITY OF WATER IN JAMES CREEK, MONROE COUNTY, MISSISSIPPI,
Geological Survey, Jackson, MS. Water Resources Div.
G. A. Bednar.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $4.00 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-1181, 1981. 28 p, 4 Fig, 2 Tab, 13 Ref.

Descriptors: *Water quality, *Surface water, *Streamflow, *Path of pollutants, Low flow, Hydrologic data, Water temperature, Heavy metals, Pesticides, Water analysis, *Mississippi, Monroe County, James Creek.

A short-term quality-of-water study of James Creek near Aberdeen, Mississippi was conducted on November 14-16, 1978, during a period of low streamflow. During the study, the water in the 2.6-mile stream reach was undesireable for many uses. Wastewater inflow immediately upstream of the study area contributed to the dissolved-solids load in James Creek. The specific conductance of the water ranged from 775 to 890 micromhos at the head of the study reach and from 650 to 750 micromhos at the end of the study reach. A substantial biochemical oxygen-demand was evident in James Creek. Five-day biochemical oxygen demand values downstream of a sewage disposal pond outfall ranged from 8.3 to 11 milligrams per liter and dissolved-oxygen concentrations ranged from 0.4 to 4.5 milligrams per liter. Nitrogen and phosphorus compounds and fecal bacteria densities were highest downstream. Total ammonia nitrogen and phosphorus concentrations in the water leaving the study area ranged from 0.29 to 1.4 milligrams per liter and from 0.65 to 1.7 milligrams per liter, respectively. Fecal coliform densities exceeding 50,000 colonies per 100 milliliters of sample were observed in the study area. The median fecal coliform density of the water leaving the study area was 2,800 colonies per 100 milliliters. (USGS)

AN EVALUATION OF THE EFFECTS OF ACID RAIN ON LOW CONDUCTIVITY HEADWATER STREAMS IN PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
J. R. Ritter, and A. E. Brown.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $7.00 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-1025, September 1981. 53 p, 10 Fig, 5 Tab, 7 Ref.

Descriptors: *Acid rain, *Water quality, *Comparison studies, *Streams, Low flow, Data collections, Water analysis, Chemical reactions, Alkalinity, Hydrogen ion concentration, Conductivity, Sulfates, *Pennsylvania, Delaware River basin, Susquehanna River basin, Ohio River basin.

Analyses of water collected at 32 sites on headwater streams in Pennsylvania during low-flow conditions in 1979-80 were compared to pre-1971 data to evaluate whether acid rain had changed the chemistry of the streams in the previous decade. Most pH, alkalinity, and sulfate values of the samples collected in 1979-80 fell within the ranges of values for samples collected before 1971. The limited data indicate, however, that pH may have increased and alkalinity and sulfate may have decreased with time. (USGS)
W82-05843

QUALITY OF WATER AND TIME OF TRAVEL IN GOODWATER AND OKATOMA CREEKS NEAR MAGEE, MISSISSIPPI,
Geological Survey, Jackson, MS. Water Resources Div.
S. J. Kalkhoff.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $5.00 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-1012, 1981. 34 p, 9 Fig, 2 Tab, 8 Ref.

Descriptors: *Water quality, *Surface water, *Streamflow, *Path of pollutants, Low flow, Hydrologic data, Water temperature, Heavy metals, Pesticides, Water analysis, Dye releases, *Mississippi, Goodwater Creek, Okatoma Creek, Time of travel.

An intensive quality-of-water study was conducted during a period of generally low streamflow in Goodwater and Okatoma Creeks near Magee, Miss. During the August 12-14, 1980, study, the mean specific conductance of the water at all sites was less than 59 micromhos per centimeter; the dissolved-oxygen concentrations were greater than 5.0 milligrams per liter: pH values ranged from 6.0 to 6.8, and the mean water temperature ranged from 23.0 to 27.0 Celsius. The biochemical oxygen demand and nutrient concentrations at the downstream sampling sites were higher in Goodwater Creek than in Okatoma Creek. The maximum 5-day biochemical oxygen demand was 2.7 milligrams per liter in Goodwater Creek and 1.5 milligrams per liter in Okatoma Creek. The mean concentration of total nitrogen was 1.0 and 0.71 milligrams per liter and the mean total phosphorus concentration was 0.26 and 0.10 milligrams per liter at the downstream sites on Goodwater and Okatoma Creeks, respectively. Fecal coliform densities generally were high at all sites, exceeding 4,000 colonies per 100 milliliters in both Goodwater and Okatoma Creeks. Objectionable concentrations of total cadmium, mercury, iron, and phenol were present in a sample of water. Dieldrin, chlordane, DDD, DDE, and DDT were present in a sample of bottom material collected at the downstream site of Okatoma Creek. The peak concentration of dye injected into Goodwater Creek traveled through a 1.7-mile reach at a rate of 0.3 mile per hour. (USGS)

QUALITY OF WATER AND TIME OF TRAVEL IN LITTLE COPIAH CREEK NEAR CRYSTAL SPRINGS, MISSISSIPPI,
Geological Survey, Jackson, MS. Water Resources Div.
S. J. Kalkhoff.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $4.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-1069, 1981. 31 p, 7 Fig, 2 Tab, 12 Ref.

Descriptors: *Water quality, *Surface water, *Streamflow, *Path of pollutants, Low flow, Hydrologic data, Water temperature, Heavy metals, Pesticides, Water analysis, Dye releases, *Mississippi, Little Copiah Creek, Time of travel.

An intensive quality of water study was conducted on Little Copiah Creek in the vicinity of Crystal

Springs, Miss., from August 19 to August 21, 1980. The quality of water in Little Copiah Creek improved 7 miles downstream of a source of wastewater inflow. The mean total nitrogen concentration decreased from 17 to 1.1 milligrams per liter and the mean total phosphorus concentrations decreased from 5.8 to 0.39 milligrams per liter. The maximum five-day biochemical oxygen demand decreased from 14 to 1.4 milligrams per liter while the dissolved-oxygen concentration increased from 2.0 to 6.9 milligrams per liter. The maximum fecal coliform and fecal streptococcus densities at the upstream sampling site were 2,200 and 6,700 colonies per 100 milliliter, respectively, and were observed to decrease downstream to 160 and 1,500 colonies per 100 milliliters. The mean stream temperatures decreased downstream only slightly from 26.5 to 25.0 Celsius and the pH of the water ranged from 7.2 to 7.4 units upstream and 6.5 to 7.0 units at the downstream site. The average rate of dye travel through the upstream 2.3 mile reach was 0.08 miles per hour during the study. (USGS)

STATISTICAL ANALYSIS TO DERIVE IMPROVED STORMWATER QUALITY MODELS,
Union Coll., Schenectady, NY. Dept. of Civil Engineering.
T. K. Jewell, and D. D. Adrian.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 489-499, May, 1982. 3 Fig, 11 Tab, 5 Ref.

Descriptors: *Rainfall-runoff relationships, *Storm water, *Water quality, Model studies, Urban runoff, Runoff, Hydrologic models, Statistical analysis, Fate of pollutants, Pollution load, Rainfall intensity.

Statistical analysis of storm water quality models revealed that no one model was consistently better than others in predicting storm water pollutant washoff. Even when the same model fit well for several basins, the estimated parameter values varied significantly among the basins. Therefore, calibration of an existing model is not advisable for predicting storm water quality. A better procedure would be to gather data from each basin under study and develop models from this data. The primary independent variables were total volume of runoff for storm total analyses and runoff intensity for instantaneous flux analyses. Also used as independent variables in selected models were storm duration, time since start of storm, particulate fallout, population density, and percentage impervious area. Fourteen models for storm event total loadings and 15 models for instantaneous flux were analyzed. (Cassar-FRC)

METAL SURVEYS IN SOUTH AFRICAN ESTUARIES. II. KNYSNA RIVER,
National Physical Research Lab., Pretoria (South Africa).
R. J. Watling, and H. R. Watling.
Water S. A., Vol 8, No 1, p 36-44, January, 1982. 5 Fig, 6 Tab, 11 Ref.

Descriptors: *Estuaries, *Trace metals, Oysters, Estuarine environment, Knysna River, South Africa, Zinc, Copper, Cadmium, Cobalt, Thesen's Island, Lead, Sediments, Monitoring, Rivers, Water pollution sources.

A survey was conducted to determine metal levels in the Knysna estuary and the rivers leading to it. Surface and bottom water samples were taken from up to 25 sites at low tide during May 1977. Metal levels in surface waters were generally higher in the river, gradually decreasing towards the national road bridge, after which concentrations remained relatively constant in the rest of the estuary. Cobalt and mercury levels did not follow this pattern. Surface sediments in the estuary demonstrated that the estuary is relatively unpolluted with respect to tract metals. Metal levels in the drain sediments were considerably higher than those in the normal estuarine sediments, as expected. Twelve sediment cores were also collected. Four sites of metal accumulation of a relatively long-lived nature were identified, including Thesen's Island point, close to the Leisure Isle resort, with high cadmium levels; and Thesen's Island jetty, where there are elevated levels of cadmium, chromium, zinc, cobalt, and nickel. It is suggested that there was once a localized source of these metals which now no longer exists. As yet the Knysna Lagoon is considered relatively unpolluted. Metal concentrations in Crassostrea gigas and Ostrea edulis from the Knysna estuary are much lower than many of the reported values for these species. (Baker-FRC)

5C. Effects Of Pollution

ACID PRECIPITATION. 1. CAUSES AND CONSEQUENCES,
Environmental Law Inst., Washington, DC.
H. Babich, D. L. Davis, and G. Stotzky.
Environment, Vol 22, No 4, p 6-13, 40-41, May, 1980. 4 Fig, 1 Tab, 74 Ref.

Descriptors: *Acid rain, Air pollution, Rainfall, Air pollution effects, *Environmental effects, Aquatic environment, Ecosystems, *Hydrogen ion concentration, *Ecological effects.

The causes of acid precipitation are detailed and its consequences for the abiotic and biotic components of the terrestrial and aquatic ecosystems and for natural and man-made materials are described. Acid precipitation is defined as rain or snow with pH values of less than 5.6. The incidence and severity of acid precipitation falling over the United States, Canada, and most of western Europe had increased significantly within the last 20 to 25 years. Acid precipitation is associated with industrial and automotive emissions of sulfur oxides, nitrogen oxides, and gaseous hydrogen chloride resulting from the combustion of fossil fuels. These pollutants may remain in the atmosphere for several days, during which they may be transported large distances, sometimes exceeding 500 miles, before being deposited on water or land surfaces. Acid precipitation may have a toxic effect on indigenous plants and animals by altering the chemical composition of the land or aquatic environments on which it is deposited. Soil type is a factor in determining the susceptibility of terrestrial environments to acid precipitation. The pH of some soils may be lowered, or the leaching of calcium, magnesium, or heavy metals from the soil may be accelerated. In addition, acid rain may adversely affect the reproductive success of some terrestrial animals and cause a variety of plant growth and foilage damage problems. The pH of lakes or streams may be lowered, resulting in the release of toxic heavy metals, the disappearance of fish populations, a reduction in the microbial decomposition processes, and a general lowering of the fertility of the aquatic ecocystem. Acid precipitation has also been shown to promote the corrosion of metals, particularly iron and iron-containing alloys, and the deterioration of stone and marble sructures. (Carroll-FRC)

KINETIC MODELING OF THE OZONATION OF PHENOL IN WATER,
Vanderbilt Univ., Nashville, TN. Dept. of Chemical Engineering.
J. A. Roth, W. L. Moench, Jr., and K. A. Debalak.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 135-139, February, 1981. 4 Fig, 2 Tab, 18 Ref.

Descriptors: *Kinetics, *Phenol, *Ozonation, Model studies, *Wastewater treatment, *Industrial wastewater, Mass transfer, Chemical reactions.

A model for predicting the extent of the gas-liquid reaction between ozone and phenol was developed from bench-scale studies. This is relevant to ozonation of phenols in industrial wastewater streams. Experimental data showed first-order dependence with respect to phenol. The model was fit to data obtained from semibatch and continuous stirred tank reactor studies. Analysis of data by other investigators produced model parameters which compared well with results of this study. Gram-moles of phenol removed vs, gram-moles of ozone consumed were plotted on a graph, not distinguishing between ozone reacting with phenol and intermediates and ozone which self-decomposes. For complete removal of phenol, 4-6 moles of ozone were required. (Cassar-FRC)

COSTS FOR SMALL SYSTEMS TO MEET THE NATIONAL INTERIM DRINKING WATER REGULATIONS,
North Carolina Utilities Commission, Raleigh.
R. G. Stevie, and R. M. Clark.
Journal of the American Water Works Association, Vol 74, No 1, p 13-17, January, 1982. 5 Fig, 8 Tab, 13 Ref.

Descriptors: *Costs, *Water treatment, *Economies of scale, Water quality standards, *Small water systems, Water quality control, Financing, Regulations, Water supply.

More than 95% of the water suppliers in the United States are small systems, serving fewer than 10,000 people. The increased water quality demands of the National Interim Drinking Water Regulations (NIPDWR) have a special financial impact on small systems because of their characteristics cost patterns and financing possibilities. The existence of positive economies of scale is a pervasive characteristic of water supply technology. The increasing financial burden imposed by NIPDWR will increase pressure in the direction of regionalization or joining small water companies to adjacent large ones. An analysis was undertaken of the costs of required new technolgy in 23 small water utilities from EPA regions 3,5 and 6. Seven of the utilities were determined to suffer from potential NIPDWR violations. cost impacts were calculated for proposed treatments to solve these violations. Cost increases ranted from 1.3 cents/1000 gal for chemical oxidation to remove excessive manganese to $4.18/1000 gal for lime softening to remove excessive barium. (Carroll-FRC)

FACTORS AFFECTING THE RECOVERY OF ISH POPULATIONS IN AN INDUSTRIAL RIVER,
University of Wales Inst. of Science and Technology, Cardiff. Dept. of Applied Biology.
A. W. H. Turnpenny, and R. Williams.
Environmental Pollution, Series A, Vol 26, No 1, p 39-58, 1981. 6 Fig, 6 Tab, 31 Ref.

Descriptors: *Fish populations, *Water pollution control, Water quality, Fish, Stream improvement, Toxicity, Hydrogen ion concentration, Dissolved oxygen, Industrial wastewater, *Wales, Great Britain, Ebbw Fawr.

The Ebbw Fawr is a river located in southeast Wales which was rendered virtually devoid of fish by industrial pollution over 100 years ago. Progressive improvements in water quality have been achieved since the early 1960s with the introduction of various pollution control measures. Significant water quality improvements have resulted from the installation of pollution control measures at coal washeries and a steelworks on the river in the early 1970s. These pollution control measures have been successful in reducing the levels of toxic materials in the river and in restoring dissolved oxygen levels and pH values acceptable to fish.

LIBRARY U. OF I., URBANA-CHAMPAIGN

The brown trout was the first freshwater fish species to become reestablished in parts of the river between 1974 and 1977. The trout was followed by eel, stoneloach, strickleback, and bullhead species. Calculated toxicities and the results of fish caging tests indicated that water quality was satisfactory for fish populations throughout the river, with the possible exception of a short reach immediately below the steelworks. The limited numbers of fish available for recolonization and the restrictions on their movements resulted in the failure of the fish to recolonize some upstream reaches having good water quality. Although good growth and condition factors among the recolonizing brown trout stock suggest that a sport fishery could be developed on the river, stocking with hatchery-reared fish will be necessary for some time due to residual silt pollution which inhibits spawning. (Carroll-FRC)
W82-04812

TOXICITIES OF PARAQUAT AND METRIBUZIN (SENCOR) HERBICIDES TO THE FRESHWATER COPEPODS, EUCYCLOPS AGILIS AND DIAPTOMUS MISSISSIPPIENSIS,
Southern Univ., Baton Rouge, LA. Dept. of Biological Sciences.
S. M. Naqvi, T. S. Leung, and N. Z. Naqvi.
Environmental Pollution, Series A: Ecological and Biological, Vol 26, No 4, p275-280, December, 1981. 3 Tab, 13 Ref.

Descriptors: *Herbicides, *Toxicity, *Copepods, *Water pollution effects, Aquatic animals, Crustaceans, Paraquat, Metribuzin, Bioassay, Mortality.

The acute toxicities of the herbicides, paraquat and metribuzin, on freshwater copepods were determined by 24- and 48-hour static bioassay tests. Zooplanktonic organisms were collected from Lake Kernan and acclimatized for 96 hr in 90-liter aquaria containing lake water. Copepods were separated by passing through a plankton net into a vial, where they accumulated at the top of the vial. The copepod population was comprised of 91% calanoids (Diaptomus mississippiensis March) and 9% cyclopoids (Eucyclops agilis Koch). The 24-hour LC50 values for paraquat and metribuzin were 10 and 205 ppm; the 48-hour LC50 values, 5 and 150 ppm, respectively. Mortality rates off the copepods due to herbicide exposure were dosage dependent and directly proportional to exposure time. A 1:1 mixture of the two herbicides was less toxic than paraquat and more toxic than metribuzin. LC50 values for the mixture were 29.1 ppm for 24 hours and 17.1 for 48 hours. (Cassar-FRC)
W82-04814

THE ASSESSMENT OF THE POSSIBLE INHIBITORY EFFECT OF DYESTUFFS ON AEROBIC WASTE-WATER BACTERIA, EXPERIENCE WITH A SCREENINT TEST,
Imperial Chemical Industries Ltd., Brixham (England).
D. Brown, H. R. Hitz, and L. Schaefer.
Chemosphere, Vol 10, No 3, p 245-261, 1981. 5 Fig, 8 Tab, 14 Ref.

Descriptors: *Dyes, *Activated sludge process, *Bacteria, *Water pollution effects, Wastewater treatment, Sewage bacteria, Inhibition, Respiration Oxygen uptake, *Aerobic bacteria, Industrial wastewater, Chemical wastewater.

A rapid screening test for assessing the possible inhibitory effects of dyestuffs on aerobic wastewater bacteria was developed and tested. Respiration rates of bacteria in activated sludge with and without the chemical under test were compared. Chemicals may be screened in a series at the 100 mg per liter level, or one chemical may be tested at several concentrations over the range < 1 to > 100 mg per liter. An activated sludge concentration of 1600 mg per liter, about half that in many sewage plants, was used to confine the oxygen uptake rates to a convenient range. Recommended contact time was 32 hours, and recommended pH range, 7-8. One year of testing 202 dyes showed that 19, all in the Basic Dye Group, had IC50 (50% inhibition concentrations) less than 100 mg per liter. Other groups of dyes tested were Acid, Direct, disperse, Reactive, ad Miscellaneous. The chemical 3,5-dichlorophenol was found suitable as a procedural check. (Cassar-FRC)
W82-04825

EFFECT OF MIXED LIQUOR SUSPENDED SOLIDS CONCENTRATION ON THE BIODEGRADATION OF NITRILOTRIACETIC ACID IN THE ACTIVATED SLUDGE PROCESS,
Imperial Coll. of Science and Technology London (England). Public Health Engineering Lab.
L. A. Obeng, J. N. Lester, and R. Perry.
Chemosphere, Vol 10, No 9, p 1005-1009, September, 1981. 1 Fig, 1 Tab, 21 Ref.

Descriptors: *Nitrilotriacetic acid, *Mixed liquor solids, *Biodegradation, Degradation, Wastewater treatment, *Activated sludge process, Detergents, *Heavy metals, Metals, Water pollution effects, Fate of pollutants, Chelation.

Biodegradation of nitrilotriacetic acid (NTA) and heavy metal removal were studied in a laboratory-scale activated sludge system at two concentrations of mixed liquor suspended solids (MLSS), 2000 and 4000 mg per liter. Heavy metals in the influent sewage ranged from 0.1 to 0.5 mg per liter (Cd, Cr, Cu, Ni, Pb, and Zn). A 10 mg per liter dose of NTA added to the activated sludge system produced effluent concentrations of 0 to 1 mg per liter NTA for the 4000 mg per liter MLSS and 0 to 3 mg per liter for the 2000 mg per liter MLSS. Metal levels in the effluent were lower than in the influent. Doubling the NTA levels to simulate a wash day increased effluent NTA levels to 10 mg per liter in the 2000 mg per liter MLSS and to 5 mg per liter in the 4000 mg per liter MLSS. Doubling the NTA concentration did not have any adverse effects on suspended solids or COD removal. (Cassar-FRC)
W82-04829

A ONE YEAR STUDY OF THE SEASONAL VARIATIONS OF SDDT AND PCB LEVELS IN FISH FROM HEATED AND UNHEATED AREAS NEAR A NUCLEAR POWER PLANT.
National Swedish Environment Protection Board, Stockholm.
M. Edgren, M. Olsson, and L. Reutergardh.
Chemosphere, Vol 10, No 5, p 447-452, May, 1981. 2 Fig, 2 Tab, 10 Ref.

Descriptors: *Fish, *Thermal pollution, *Chlorinated hydrocarbons, *Water pollution effects, Perch, Roach, Cooling water, Insecticides, Pesticides, DDT, Polychlorinated biphenyls, *Nuclear powerplants, Seasonal variation, Simpevarp, *Sweden.

Perch living in the heated water discharges of a nuclear power plant at Simpevarp, Sweden, had higher levels of DDT and polychlorinated biphenyls than perch in the intake areas. The difference in temperature between the two sites was 4 to 10C. No significant differences in organochlorine levels were found in roach from the two locations. Levels of DDT and polychlorinated biphenyls were highest in spring and early summer and lower in autumn. (Cassar-FRC)

EFFECTS OF SULFURIC ACID RAIN ON MAJOR CATION AND SULFATE CONCENTRATIONS OF WATER PERCOLATING THROUGH TWO MODEL HARDWOOD FORESTS,
Corvallis Environmental Research Lab., OR.
J. J. Lee, and D. E. Weber.
Journal of Environmental Quality, Vol 11, No 1, p 57-64, January-March, 1982. 5 Fig, 2 Tab, 40 Ref.

Descriptors: *Acid rain, *Forest watersheds, *Ecosystems, Percolation, Soil types, Forest soils, Forest management, Sulfuric acid, Nitric acid, Acidity, Leaching, Cycling nutrients, Water pollution sources, Groundwater, Ecological effects.

Changes are reported in pH, calcium, magnesium, potassium and sulfate ions in acid rain as it percolates through experimental forest ecosystems. The findings indicate that interaction with a well developed hardwood canopy and litter layer can significantly raise the pH and increase concentrations of basic cations in rainwater along with increasing concentrations of sulfate ions. Increased anion concentrations in soil solutions will cause increased concentrations in soil solutions, will cause increased concentrations of cations, which would immediately lead to increased leaching of basic cations from the soil and to decreases in the pH of the soil solution. Sulfuric acid rain, however, may not cause significantly higher sulfate concentrations in soil solutions until the ability of the soil to adsorb sulfate is exhausted. For a strong sulfate adsorber, this might occur after a year or two for rain at pH 4.0. The response of soil solutions to nitric acid rain could be more rapid, but lower in magnitude. The various layers of the model ecosystems responded differently to the sulfuric acid rain, emphasizing that the effects of acid precipitation on forest soils can only be adequately studied in an ecosystem context. EFFECT OF LONG TERM EXPOSURE TO PETROLEUM ON MIXED FUNCTION OXYGENASES IN FISH: FURTHER SUPPORT FOR USE OF THE ENZYME SYSTEM IN BIOLOGICAL MONITORING,
Dept. of Fisheries and Oceans, St. John's (Newfoundland).
J. F. Payne, and L. L. Fancey.
Chemosphere, Vol 11, No 2, p 207-213, 1982. 1 Tab, 30 Ref.

Descriptors: *Fish, *Oil spills, *Enzymes, *Water pollution effects, Fate of pollutants, Codfish, Flounder, Sculpin, Toxicity, Mixed function oxygenases, Oil pollution, Monitoring, Hydrocarbons.

Fish were exposed at ambient temperatures in laboratory aquariums to low levels of petroleum hydrocarbons in sediments for several months to determine mixed function oxygenase (oxidase) (MFO) response. Three species at three different stages of the sexual cycle were studied: spawning codfish (Gadus morhua), post-spawned sculpins (Myoxocephalus octodecemspinosus), and gonadally maturing flounder (Pseudopleuronectes americanus). MFO activity was elevated 4-fold in the liver and 3-fold in the gills of codfish exposed for 4 months to concentrations of 0.30-0.60 ppm petroleum at temperatures of -1 to +1 C. Liver enzyme activity remained elevated 3-fold in sculpins exposed to 0.15 to 0.20 ppm of petroleum for 3 months at 4-12 C. Using an oil-contaminated sediment weathered for 1 year induced a 7-fold level of MFO activity in flounder. Several factors that might detract from use of the MFO system in biological monitoring did not interfere. These were sex, state of sexual maturity, small number of animals, and the codfish's large fatty liver, which could possibly negate induction. (Cassar-FRC)

PETROLEUM REFINERY WASTEWATER INDUCTION OF THE HEPATIC MIXED-FUNCTION OXIDASE SYSTEM IN PACIFIC STAGHORN SCULPIN,
Northrop Services, Inc., Corvallis, OR.
J. W. Ridlington, D. E. Chapman, B. L. Boese, and V. G. Johnson.
Archives of Environmental Contamination and Toxicology, Vol 11, No 1, p 123-127, 1982. 4 Tab, 16 Ref.

Descriptors: *Industrial wastes, *Estuarine environment, Aquatic life, Pollution effects, Water quality, Enzymes, *Yaquina Bay, *Oregon, *Oil industry.

The purpose of this study was to establish the presence of cytochrome P-450 and mixed function oxidase (MFO) in the ubiquitous estuarine sculpin, Leptocottus armatus, and to determine whether induction of these enzymes occurs as a result of exposure to petroleum refinery wastewater. Immature Pacific staghorn sculpin were collected from tidal channels in Yaquina Bay, Oregon, by 15 meters beach seine. Wastewater was collected from two Class B refineries and stored at 1 to 4

degrees C. The microsomal cytochrome P-450 linked mixed function oxidase system was found to be present in staghorn sculpin. The increase in cytochrome P450 in response to beta-naphtholflavone injection indicated that at least part of this system is inducible by an aromatic hydrocarbon known to induce MFO activity in other fish. Different wastewaters were able to induce sculpin MFOs to different degrees, probably due to differences in aromatic hydrocarbon content. (Baker-FRC)

THE NEW POLLUTION--GROUNDWATER CONTAMINATION,
D. E. Burmaster.
Environment, Vol 24, No 2, p 6-13, 33-36, March, 1982. 2 Fig, 7 Tab, 35 Ref.

Descriptors: *Groundwater pollution, *Organic compounds, *Public health, Fate of pollutants, Water pollution sources, Regulations, Chlorinated hydrocarbons, Wells, Water supply, Drinking water, Carcinogens, Risks, Water quality standards, Water pollution effects.

Groundwater, considered in the past to be a pristine resource, is vulnerable to contamination from human activities: surface impoundments, landfills, agriculture, leaks and spills, land disposal of wastewater, septic tanks, mining, petroleum and gas production, and injection wells. Once contaminated with nonbiodegradable organic chemicals, groundwater may remain so for hundreds or thousands of years. The degree of threat to groundwater depends on local geology and hydrological conditions. If plumes of pollution move very slowly, it may take decades for contamination to reach a water supply. Monitoring this movement is very expensive. Toxic organic chemicals have been found in many municiplal and private wells throughout the U.S. Areas with major problems are states east of the Mississippi River and several sparsely populated western states. Crude estimates of cancer risks from using water from chemically-contaminated wells were possible in a few cases. In Nassau County, Long Island, where groundwater contains high levels of chlorinated hydrocarbons and other organic chemicals, it is estimated that a additional 750 people out of a million population will contract cancer in their lifetimes as a result of exposure to these chemicals in drinking water. The EPA has adopted maximum contaminant levels for pollutants in drinking water for a few substances, including trihalomethanes, but for most of the synthetic organic compounds found in groundwater supplies there are no proposed standards to date. BENTHOS AND ZOOPLANKTON OF COAL STRIP MINE PONDS IN THE MOUNTAINS OF NORTHWESTERN COLORADO, U.S.A.,
Colorado State Univ., Fort Collins. Dept. of Zoology and Entomology.
S. P. Canton, and J. V. Ward.
Hydrobiologia, Vol 85, No 1, p 23-31, 1981. 3 Fig, 4 Tab, 29 Ref.

Descriptors: Invertebrates, Mine drainage, Water quality, *Strip mine wastes, *Benthos, Benthic fauna, *Zooplankton, *Colorado, Physicochemical properties, *Ponds, Water pollution effects, Species diversity, Spoil banks, Aquatic fauna, Coal mines, Ecological effects.

Zooplankton, benthic fauna, and physicochemical parameters were studied in four ponds in a coal strip mine region of northwest Colorado from July 1977 to May 1978. Pond 1, age 10 years, received mine drainage. Pond 2, age over 30 years, received mine drainage. Pond 3 received partial mine drainage. Pond 4, control, received no mine drainage. The spoils ponds received no acid mine drainage (pH of all ponds, 7.4-7.6) but were higher in total dissolved solids, nitrate, and sulfate than the control pond. The younger spoils pond was lowest in zooplankton density and diversity, but benthic invertebrates were highest in Pond 1, decreasing in order through Pond 4. Pond 1 contained few or no Cladocera, Trichoptera, Amphipoda, Hydracarina, and Sphaeriidae. It is believed that the younger spoils pond had lower density and diversity because colonizers did not yet have the opportunity to become established because of either distance or time. In addition, nitrate, sulfate, and total dissolved solids levels in Pond 1, although higher than in the other ponds, were not outside tolerable limits for the aquatic species. (Cassar-FRC)

ECOLOGICAL EFFECTS OF URBAN STORM-WATER RUNOFF ON BENTHIC MACROINVERTEBRATES IHIBITING THE GREEN RIVER, MASSACHUSETTS,
Massachusetts Univ., Amherst, Dept. of Environmental Sciences.
J. M. Pratt, R. A. Coler, and P. J. Godfrey.
Hydrobiologia, Vol 83, No 1, p 29-42, 1981. 1 Fig, 6 Tab, 17 Ref.

Descriptors: *Storm runoff, Rivers, *Massachusetts, Benthos, Runoff, Storm water, *Urban runoff, Aquatic life, Population dynamics, Aquatic populations, Water pollution, *Green River, *Ecological effects.

The purpose of this study was to investigate the long term effects of urban runoff on the benthic community in the Green River, Massachusetts. The Green River originates in south-central Vermont and flows in a southerly direction, 32 km before joining the Deerfield River near Greenfield, Massachusetts. The water quality is typically good upstream but deteriorates immediately after passing through an urban reach. Four analytical procedures were used: species diversity (the Brillouin index), hierarchical diversity, major taxa composition, and collection dissimilarity at the species level. The overall results from these four analytical studies strongly indicated that the macrobenthic community became progressively disrupted downstream in the urban reach. The high degree of correspondence between the known sources of urban runoff and the observed effects on the benthic community are forceful arguments that urban runoff is the casual agent of disruption. The impact is not confined to periods following heavy rains. The stress was heaviest in the summer low flow and was probably localized in or near the stream bed. Monitoring of physical, chemical, and biological parameters should be undertaken to understand the stream bed microzone. Urban runoff pollutant loading standards must take into account the apparent long term residence of pollutants in the substrate and the associated stress of summer low flows. (Baker-FRC)

RARE AND ENDANGERED SPECIES: FRESHWATER GASTROPODS OF SOUTHERN NEW ENGLAND,
Connecticut Univ., Storrs.
E. H. Jokinen, and J. Pondick.
Bulletin of the American Malacological Union, 1981, p 52-53, 1 Tab, 6 Ref.

Descriptors: Snails, *Endangered species, Connecticut, *Gastropods, Cincinnatia cincinnatiensis, Amnicola walkeri, Pomatiopsis lapidaria, Goniobasis virginica, *Acid rain, Air pollution fallout, *New England, *Ecological effects, Endangered species.

The rare and endangered species of freshwater gastropods of southern New England are reported on based upon data collected over the past four years. Field sampling was concentrated in Connecticut but included parts of southern Massachusetts east to Cape Cod (69 55 W to 73 45'W, 40 00'N). Water chemistry data were collected along with the snails. Collection methods and water analysis techniques have been described elsewhere by Jokinen (The Nautilus 92:156-160, 1978). Voucher specimens have been placed in the Museum of Comparative Zoology, Harvard University, the Florida State Museum, and the Museum of Zoology, the University of Michigan. Acid rain poses a threat to poorly buffered habitats.

TOXICITY OF ANAKEESTA FORMATION LEACHATES TO SHOVEL-NOSED SALAMANDER, GREAT SMOKY MOUNTAINS NATIONAL PARK,
Tennessee Technological Univ., Cookeville.
R. C. Matthews, Jr., and E. L. Morgan.
Journal of Environmental Quality, Vol 11, No 1, p 102-106, January-March, 1982. 2 Fig, 2 Tab, 31 Ref.

Descriptors: *Leachates, *Toxicity, Highways, *Highway effects, Infiltration, Percolation, Water pollution sources, *Salamanders, *Great Smoky Mountains National Park.

In 1963 following relocation of U.S. Highway 441 near Newfound Gap in the Great Smoky Mountains National Park, aquatic life in a headwater stream, Beech Flats Prong, was severely disrupted. Attempts to restock the stream with brook trout at various times after highway completion failed. Toxic substances were not identified until almost a decade later in leachate from roadfill materials consisting of pyrite-containing Anakeesta rock. Toxic metals, especially Al and lesser quantities of Cu and Zn, are dissolved and transported by acidic leachates generated by redox actions of metal sulfides. The toxicity of leachates produced in the laboratory from Anakeesta rock and stream reference water was investigated in 96-hr bioassays with the shovel-nosed salamander, Leurognathus mamoratus, abundant in the park. After 48 hr of exposure at leachate concentrations of about 50%, mortality of about half of the salamanders present occurred. The mortality rate was a function of exposure time and concentration. The exact mechanism of death is unknown. Similar problems may be anticipated in other areas where this type of rock formation occurs. (Baker-FRC)

THERMAL FRONT FORMATION FROM BUOYANT SURFACE JETS,
Alaska Univ., Fairbanks. Geophysical Inst.
J. P. Gosink.
Journal of the hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No Hy2, p 252-257, February, 1982. 2 Fig, 17 Ref.

Descriptors: *Thermal water, *Powerplants, *Froude number, *Mathematical studies, *Thermal pollution, *Jets, Electric powerplants, Nuclear powerplants, Water pollution effects, Thermal powerplants, Heated water, Waste heat, Temperature effects, Temperature gradient.

Electric generating plants powered by nuclear or fossil fuels produce waste heat that is usually released into a stream or water basin as a horizontal buoyant jet causing great elevations in temperature in the receiving waters. Concentric thermal waves also radiate from such outfalls. An attempt was made to explain the formation of thermal fronts for outfall Froude numbers in the range of F less than or equal to 3.3. Using experimental and theoretical data, it was demonstrated that the homogeneous round jet has a characteristic natural frequency in

LIBRARY U. OF I., URBANA-CHAMPAIGN

the range 0.3 > Strouhal number < 0.5 which is damped out beyond the ration of some distance x/D (the jet diameter) greater than or equal to 5. Instabilities in the form of thermal fronts may increase and spread radially from the outfall if the brunt-Vaisala frequency of the ambient basin near the outfall is greater than or equal to the characteristic jet frequency. These findings may be useful in designing warm water diffusers. To minimize the occurrence to steep thermal gradients associated with thermal fronts, outfall Froude numbers < 3.3 should be avoided. More research into the behavior of thermal fronts is needed to protect aquatic organisms from the steep gradients of temperature that may occur with the passage of a thermal front and may be linked to a given range of outfall froude number. PESTICIDE EFFECTS ON AQUATIC HABITATS,
Hamburg Univ. Inst. fuer Hydrobiologie und Fischereiwissenschaft (Germany, F.R.).
C. W. Heckman.
Environmental Science and Technology, Vol 16, No 1, p 48A-57A, January, 1982. 3 Tab, 42 Ref.

Descriptors: *Pesticides, *Aquatic habitats, Ecosystems, Aquatic environment, Agricultural chemicals, *Ecological effects.

Only a small percentage of the studies of the effects of pesticides have addressed the effects of pesticides on aquatic habitats. Water bodies may be affected by contamination from persistent agricultural chemicals which find their way into nearby water bodies, from direct application to rice fields or marshes, from wastewater released to water bodies, or from localized direct applications to make a water body more suitable for a selected purpose. Application of pesticides to orchards or other agricultural land may drastically reduce both the number of species and the numbers of individuals within each species remaining in adjacent drainage ditches or other water bodies. Pesticides which find their way into water bodies frequently eliminate food organisms for the fish, such as insects, small crustaceans, or rotifers, leading to subsequent reductions in fish populations. Many agricultural pesticides which are subject to severe use restrictions in industrial countries continue to be used in developing countries, where there are few persons trained to evaluate the ecological stresses on biota or their effectiveness in meeting agricultural objectives. Some of the problems caused by extensive pesticide application programs in these countries could be avoided if the international development aid organizations which finance these efforts would provide adequate monitoring programs and planning support. EFFECTS OF ACID PRECIPITATION,
Environmental Protection Agency, Corvallis, OR.
N. R. Glass, D. E. Arnold, J. N. Galloway, G. R. Hendrey, and J. J. Lee.
Environmental Science and Technology, Vol 16, No 3, p 162A-169A, March, 1982. 4 Fig, 4 Tab, 23 Ref.

Descriptors: *Acid rain, *Environmental effects, Sulfuric acid, Pollution effects, Water pollution sources, Reviews, Public health, Appalachian Mountains, Coal, Fuel, Lakes, Ecological effects.

Acid precipitation has become a widespread problem due to the ubiquitous nature of the pollution sources cntributing to acid precipitation and the ease with which the emissions causing it are carried by moving air masses. Serious symptoms of acidification have been documented in lakes of New York's Adirondack Mountains, far removed from any industrial activity. While precipitation is most acidic in the northeast US, the geographic extent of the problem encompasses the southeast and portions of the midwest and far west. A growing body of evidence suggests that acid precipitation adversely affects public welfare through loss of fish and other aquatic life, increased leaching of nutrient cations from the soil, possible reductions in crop and forest productivity, and the release of heavy metals or nutrients from rocks, soils and lake and stream bottom sediments. Research on aspects of acid rain is reviewed. The sensitivity of surface water bodies to acid precipitation was evaluated, and historical changes in surface waters were documented. (Baker-FRC)

ENZYMES AND OTHER BIOCHEMICAL INDICATORS OF TOXICANT EFFECTS IN FISHES,
National Marine Fisheries Service, Ann Arbor, MI. Great Lakes Fishery Lab.
D. R. M. Passino.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 19-43, 3 Fig, 2 Tab, 14 Ref. 3 Append.

Descriptors: *Bioassay, *Bioindicators, *Enzymes, *Fish, *Water pollution, Pollutants, Pesticides, Lead, Mortality, Chlorinated hydrocarbons, Growth, Population dynamics, Polychlorinated biphenyls, DDE, Dieldrin, Chlordane, *Pollutant identification.

Enzymes and reproductive hormones may be used as biochemical indicators of toxicant effects in aquatic organisms. Lake trout in the Great Lakes have suffered a serious population decline caused by excessive fishing and predation, but also possibly by the effects of pollutants, since natural reproduction of planted fish is almost non-existent. Two fish enzymes have been identified as indicators of specific contaminants or classes of contaminants. Acetylcholinesterase is inhibited by organophosphate insecticides, while lead inhibits delta-amino levulinic acid dehydratase. Detoxifying enzymes, which are induced when an organism is exposed to toxic substances, have been recognized in fish. Lake trout fry mortality was 40.7% when they were exposed to simulated Lake Michigan levels of PCB and DDE, 10 ng/l and 1.0 ng/l, respectively. A slight increase in growth was observed in the exposed fish. A similar increase in growth was observed in lake trout eggs and fry exposed to simulated Lake Michigan levels of organochlorines, 1 ng/l PCB, 0.2 ng/l DDE, 1 ng/l dieldrin, and 0.9 ng/l technical grade chlordane. The exposed fish had a higher RNA/DNA ratio than the controls, supporting the trend towards increased growth. Reproductive and steroid hormones have been shown to be affected by contaminants. The baseline levels for such chemicals are not known, nor are the effects of season, spawning and migration, so these biochemical indicators can not be used with any certainty yet. (Brambley-SRC)

OVERVIEW AND ASSESSMENT OF BIOLOGICAL SENSING,
Environmental Protection Agency, Washington, DC. Office of Research and Development.
J. D. Koutsandreas.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 45-54.

Descriptors: *Biomonitoring, *Ecosystems, *Aquatic life, *Bioassay, Bioaccumulation, Hazardous materials, Environmental effects, Bioindicators, Water pollution, Air pollution, Soil contamination, Evaluation.

The Environmental Protection Agency is evaluating six approaches to biomonitoring: in-situ bioassays; bioaccumulation; indicator organisms; community and population changes; species health; and integration of biological methods to determine release of toxic substances from hazardous waste operations for air, water, and land. Biological monitoring is defined as the use of a living organism to measure, for a specific time and location, the presence or amount of a substance in the environment or in man, or the effect of a substance on the environment or man. The organism may be a naturally present or introduced species in the environment, or in the laboratory, or in a simulated environment or microcosm. Biological monitoring offers great promise for detecting specific chemicals and has the advantages of greater biological relevance, greater sensitivity, and ability to indicate actual or potential exposures. Most of the emphasis has been on monitoring of aquatic systems, but biological monitoring can be applied to air and terrestrial systems. (Brambley-SRC)

METABOLIC RESPONSE OF FISH TO STRESS,
Texas Univ. at Austin, Port Aransas. Marine Science Inst.
D. E. Wohlschlag.
In: 2nd Interagency Workshop on In-Situ Water-Quality Sensing: Biological Sensors, April 28-30, 1980, Pensacola Beach, Florida. National Oceanic and Atmospheric Administration Report, 1981. p 119-141, 11 Fig, 35 Ref.

Descriptors: *Fish, *Fish behavior, *Metabolism, *Monitoring, *Sublethal effects, *Environmental effects, Water pollution effects, Pollutants, Toxicity, Industrial wastes, Salinity, Water temperature.

Fish may be used to monitor consistency of water quality; establish optimal natural environmental conditions; assess and monitor normal, or sublethal departures from normal, conditions with respect to optimal natural environments; assess and monitor deleterious sublethal stress effects of toxic materials; and predict the long-term outcome of natural or anthropogenic stresses at sublethal levels. Before being used in monitoring tests the standard, routine, and active metabolic rates must be determined on acclimatized fish. Using spotted sea trout, red snapper, and striped mullet, experiments have shown the effects of temperature, salinity, red tide exposure, chronic pollution, and ocean dumped petrochemical waste and pharmaceutical waste on metabolic rates and swimming performance. The metabolic rates declined in proportion to the stress. It may be possible to utilize more or less continuous operations to measure swimming rates and general swimming performances in clean and polluted waters. In appropriate equipment other behavior may be observed and the information added to the knowledge of general bioenergetics of fish populations. (Brambley-SRC)

CYANOBACTERIAL BLOOMS: CARBON AND NITROGEN LIMITATION HAVE OPPOSITE EFFECTS ON THE BUOYANCE OF OSCILLATORI,
State Univ. of New York Coll. at Purchase.
A. R. Klemer, J. Feuillade, and M. Feuillade.
Science, Vol 215, No 4540, p 1629-1631, March 26, 1982. 2 Fig, 27 Ref.

Descriptors: *Eutrophication, *Limiting factors, *Algae, Nitrogen, Carbon, Oscillatoria, Nutrients, Lakes, *Cyanophyta, Buoyancy.

Relative gas vacuolation (RGV) and buoyancy in blue-green algae depend on an interaction of light and limiting nutrients that affects relative rates of photosynthesis, growth, and gas-vesicle synthesis. To study dynamics of surface bloom developments, RGV was measured nephelometrically with a modified version of Walsby's technique. After a reduction in the dilution rate of a N-limiting cyclostat, RGV in Oscillatoria rubescens declined along with cell N content, and then stabilized as N content continued to decline. A companion culture was supplied by the same peristaltic pump, but deprived of carbon dioxide by a trap installed in the air line after the reduction in dilution rate. With the removal of carbon dioxide, RGV remained stable at first and then increased as the culture became increasingly limited by inorganic carbon. The effect of carbon dioxide deprivation was also noted in two intially N-limiting cyclostats with constant dilution rates. It was concluded that the relative gas vacuole content of the cell of 0. rubescens decreased with increased N limitation and increased with transitions to inorganic limitation. It is suggested that N limitation has a role in the formation of subsurface population maxima by certain species and that inorganic carbon limitation can contribute to the formation or maintenance of surface blooms. N limitation could promote increased turgor pressure and gas-vesicle collapse by contributing to the accumulation of osmotically active photosynthate, whereas the relief of N limitation would increase the assimilation of photosynthate and would reduce turgor pressure. ENTRAINMENT MORTALITY OF ICHTHYOPLANKON: DETECTABILITY AND PRECISION OF ESTIMATES,
Oak Ridge National Lab., TN.
D. S. Vaughan, and K. D. Kumar.
Environmental Management, Vol 6, No 2, p 155-162, 1982. 3 Fig, 18 Ref.

Descriptors: *Entrainment, *Powerplants, *Fish, Mathematical studies, Environmental effects, Mortality, Monitoring, Sampling, *Intakes.

The purpose of this paper is to show how a biologist may get the maximum information from entrainment sampling by controlling those aspects of sampling over which he has some control. To aid in the design of a more useful sampling program, a method is presented which examines the interrelationships among the following six variables: sample size at the intake and discharge sampling stations, fractions alive in the intake sample, population mean of entrainment mortality fraction, minimum detectable entrainment mortality, width of the confidence interval, and power of the statistical test. Only the first two are under the control of the biologist. The value of the method presented is that it interrelates controllable aspects of the sampling procedures in a manner that permits achievement of a specified level of detectable entrainment mortality, a specified width of a confidence interval, or a specified level of statistical power. Increasing sample size and/or decreasing sampling mortality will decrease the minimum detectable entrainment mortality, confidence interval width, and type II error for a given level of type I error. SEASONAL TEMPERATURE AND POWER PLANT CHLORINATION EFFECTS ON ESTUARINE INVERTEBRATES,
Academy of Natural Sciences of Philadelphia, Benedict, MD. Benedict Estuarine Research Lab.
S. L. Margrey, D. T. Burton, and L. W. Hall, Jr.
Archives of Environmental Contamination and Toxicology, Vol 10, No 6, p 691-703, December, 1981. 6 Fig, 3 Tab, 29 Ref.

Descriptors: *Chlorination, *Thermal stress, *Estuaries, *Invertebrates, Estuarine environment, Temperature effects, Seasonal variation, Powerplants, Coastal streams, Eastern United States.

This study investigated the effect of seasonal variations in temperature on the responses of two estuarine invertebrates to interacting chlorine, changes in temperature, and exposure duration conditions simulating powerplant condenser entrainment and effluent discharge conditions. The species selected, opossum shrimp and amphipods, are major food sources for higher organisms along the East Coast of the United States. The situations studied included seasonal temperatures ranging from 15 to 22C; total residual chlorine values of 0.00, 0.15, and 0.30 milligrams per liter; changes in temperature of 2, 6 and 10C; and exposure durations of 0.08, 2.0, and 4.0 hours. The two crustaceans showed a range of sensitivity when tested at various seasonal temperatures. Opossum shrimp were found to be sensitive to powerplant chlorination conditions at both acclimation temperatures, while amphipods were fairly tolerant under the same conditions. Seasonal temperature was an important factor influencing the toxicity of simulated powerplant effluents to these species, with greater mortality occurring at higher seasonal temperatures than at lower temperatures. Seasonal temperature was only a marginal factor in the mortality rates for amphipods. It is suggested that powerplants consider regulating conditions to minimize changes in temperature and total residual chlorine during the summer months in order to minimize the effects on estuarine aquatic invertebrates. IMPACT OF HEXAZINONE ON INVERTEBRATES AFTER APPLICATION TO FORESTED WATERSHEDS,
Georgia Univ., Athens. Dept. of Poultry Science.
D. T. Mayack, P. B. Bush, D. G. Neary, and J. E. Douglass.
Archives of Environmental Contamination and Toxicology, Vol 11, No 2, p 209-217, 1982. 5 Fig, 4 Tab, 24 Ref.

Descriptors: *Invertebrates, *Forest watersheds, *Herbicides, Water pollution effects, Hexazinone, Aquatic animals, Species composition, Species diversity, Fate of pollutants, *Chattahoochee National Forest, *Georgia, Macroinvertebrates, Pesticide residues, Accumulation, Bioaccumulation, Forest soils, Aquatic plants, Macrophytes, Ecological effects.

The effect of the herbicide hexazinone (useful in reforestation) on aquatic macrophytes and aquatic and terrestrial invertebrates was assessed in the Chattahoochee National Forest, Georgia. Pelletized hexazinone was applied at the rates of 16.8 kg per ha to four small watersheds in the forest on April 23, 1979. One untreated watershed served as a control. During the 8-month monitoring period hexazinone levels in samples of stream water were generally below the 1 ppb detection limit except for three peaks of 10 to 40 ppb in July-August and three very minor peaks at other times. The peaks did not appear to be correlated with storms. Traces of hexazinone or metabolites were found in aquatic macrophytes on a few occasions. The forest floor litter contained residues of hexazinone and metabolites for about 90 days after application. The highest level was 0.18 + or - 0.19 ppm hexazinone (dry weight basis) and 0.10 + or - 0.17 ppm metabolite 5 days after the first rainfall. No major changes in species composition or diversity were detected in aquatic or terrestrial invertebrates. Most samples of aquatic and terrestrial invertebrates contained no detectable herbicide residues. On a few occasions there were detectable hexazinone and/or metabolites at average levels of less than 2 ppm (wet weight basis). (Cassar-FRC)

ALGAL CONDITIONS IN THE CALOOSAHATCHEE RIVER (1975-79) LAKE OKEECHOBEE TO FRANKLIN LOCK, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
B. F. McPherson, and H. R. La Rose.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-192345, Price codes: A03 in paper copy, A01 in microfiche.
Geological Survey Water-Resources Investigations 81-81, 1982. 28 p, 7 Fig, 7 Tab, 10 Ref.

Descriptors: *Algae, *Cyanophyta, *Water quality, *Streams, Algal growth, Eutrophication, Nutrients, Phytoplankton, Flow, Seasonal variation, *Florida, *Caloosahatchee River.

Maximum numbers of suspended algae occurred in late spring and early summer, in each of the years 1975-79, in the Caloosahatchee River. Numbers exceeded 100,000 cells per milliliter at all stations sometime during the study. Concentrations decreased during late summer and autumn and were low during winter, except in January 1979 when numbers at most sites exceeded 100,000 cells per milliliter. The January 1979 bloom coincided with large discharges from Lake Okeechobee. During previous winters, discharges and algal numbers were lower. During other seasons, algal blooms occurred most frequently under low-flow or stagnant conditions. The upstream site at Moore Haven, which had the least discharge and was most stagnant, had consistently higher algal concentrations than downstream sites. Blue-green algae were dominant in the river during the summer at the upstream site throughout the year. The percentage of blue-green algae decreased downstream. Concentrations of nitrite plus nitrate nitrogen were inversely correlated with concentrations of algae and decreased to near zero during algal blooms. The low concentrations of these forms of inorganic nitrogen relative to other major nutrients probably favor blue-green algae and limit growth of other algae. Contributions by the basin tributaries to the nutritive condition of the river were small because concentrations of nutrients, algal growth potential, and algae in the tributaries were generally less than those in the river. A PRELIMINARY APPRAISAL OF THE EFFECTS OF AGRICULTURE ON STREAM QUALITY IN SOUTHWEST GEORGIA,
Geological Survey, Doraville, CA. Water Resources Div.
D. B. Radtke, J. B. McConnell, and W. P. Carey.
Geological Survey Water Resources Investigation Open-File Report 80-771, August 1980. 40 p, 15 Fig, 6 Tab, 18 Ref.

Descriptors: *Agricultural chemicals, *Water quality, *Water pollution effects, *Data collections, Sampling, Streams, Surface runoff, Agricultural watersheds, Water quality standards, Water analysis, Pesticides, Organic compounds, Inorganic compounds, Sediment yield, *Georgia, *Agricultural runoff.

Water-quality and suspended-sediment samples were collected in two basins in southwest Georgia

LIBRARY U. OF I., URBANA-CHAMPAIGN

to identify current or potential water-quality problems resulting from agricultural practices. Samples were collected monthly and during periods of storm runoff from December 1976 through July 1978. Concentrations of chemical constituents relevant to agricultural practices were found to be low, even during periods of storm runoff. Concentrations of total nitrogen and total phosphorus ranged from 0.30 to 1.60 and 0.01 to 0.42 milligrams per liter, respectively. Copper, arsenic, lead-mercury, and zinc concentrations were low and did not exceed Georgia or U.S. Environmental Protection Agency (1977) standards for safe drinking water. Concentrations of suspended sediment and total nitrogen were found to remain relatively constant over a wide range of water discharge. Concentrations of total phosphorus showed a better relation to water discharge at Little River near Lenox than at Spring Creek near Iron City. Dissolved-solids concentrations in both streams generally decreased with an increase in water discharge. Average annual yields of selected consitituents were low. Total nitrogen and total phosphorus yields were 0.60 to 0.63 and 0.04 to 0.06 tons per year per square mile in Little River and Spring Creek basins. Atrazine, butylante, and ethroprop pesticides were detected at concentrations up to 0.91 micrograms per liter in storm-runoff samples collected during the active farming season. (USGS)

THE RIVER TAME--A SHORT HISTORY OF WATER POLLUTION AND CONTROL WITHIN AN INDUSTRIAL RIVER BASIN,
Severn-Trent Water Authority, Birmingham (England).
N. Harkness.
Water Science and Technology, Vol 14, No 1/2, p 153-165, 1982. 4 Fig, 3 Tab, 11 Ref.

Descriptors: *History, *Water pollution control, *Water quality control, Wastewater treatment, Water pollution effects, Birmingham, *England, *Tame River, Urban areas, Rivers, Industrial wastes, River Tame.

Severe pollution of the River Tame, near Birmingham, England, was evident by 1872, when the river water was judged no longer safe for drinking. Legal action was taken about 1870 to prevent sewage disposal in the river and to prevent odors arising from existing wastewater treatment processes. Coal gas works, iron manufacturing, domestic sewage, and paper mills were the main sources of pollution. Many fish kills were recorded during the latter part of the 19th century. The Birmingham Tame and Rea District Drainage Board was established in 1877 to cover pollution control for the region, with its population of 476,000. Nevertheless, pollution, complaints, and legal actions continued, so that by 1918 the river was an open sewer, supporting no fish life. Industrial and domestic wastes continued to pour into the river after World War II. Since then several pollution control measures have imported water quality. Gas manufacturing ceased in 1960, sewage treatment plants were built and improved, sewer overflows were reduced, and purification lakes were built. These measures have been reflected in an increase in the number of species and abudance of fish. (Cassar-FRC)

THE AQUATIC TOXICITY OF ORGANIC COMPOUNDS TO EMBRYO-LARVAL STAGES OF FISH AND AMPHIBIANS,
Kentucky Water Resources Research Inst., Lexington.
J. A. Black, W. J. Birge, W. E. McDonnell, A. G. Westerman, and B. A. Ramey.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224601, Price codes: A04 in paper copy, A01 in microfiche. Research Report No 133, 1982. 68 p, 3 Fig, 15 Tab, 43 Ref. OWRT B-071-KY(1), 14-34-0001-0223.

Descriptors: Embryos, Larvea, *Organic compounds, Water quality, *Toxicity, *Larvae, Benzene, Phenol, Toluene, *Fish, *Embryo-larval tests, Predictive toxicology, Aquatic toxicity tests, Amphibians.

Aquatic toxicity tests were conducted on 11 organic compounds considered hazardous to water resources. The toxicity of each compound was evaluated using embryo-larval stages of up to eight fish and amphibian species. Exposure was initiated at fertilization and maintained through 4 days posthatching. The animal test species exhibited varying degrees of sensitivity to the selected toxicants. Combined frequencies for mortality and teratogenesis at 4 days posthatching gave LC-50 ranges of 3.66 to 8.25 mg/L for benzene, 1.16 to 22.42 mg/L for carbon tetrachloride, 0.11 to 1.20 mg/L for chlorogenzene, 2.03 to 68 mg/L for chlorogrorm, 3.01 to 5.56 mg/L for 1,2 dichlorobenzene, 2.54 to 34 mg/L for 1,2 dichloroethane, 13.16 to 48 mg/L for methylene chloride, 0.002 to 0.64 mg/L for nitrobenzene, 0.04 to 32 mg/L for phenol, 0.02 to 0.85 mg/L for toluene, and 3.53 to 3.77 mg/L for m-xylene. The species which exhibited the greatest susceptibility to organic compounds were the rainbow trout, Rana pipiens, and Rana temporaria. The more sensitive amphibian species generally were those which normally are restricted to aquatic or moist terrestrial habitats, whereas the more tolerant amphibians included those semi-aquatic and terrestrial species which appear to be more broadly adapted ecologically. Of the 11 test compounds, nitrobenzene, toluene, chlorobenzene, and phenol were the most toxic. The least toxic organics included dicloroethane and methylene chloride. For three chlorinated alkanes, including methylene chloride, chloroform, and carbin tetrachloride toxicity was found to increase with the degree of chlorination.

THE EFFECTS OF LAND-CLEARING ON A SMALL WATERSHED IN SOUTHERN GUAM,
Guam Univ., Agana. Water and Energy Research Inst.
C. P. Neubauer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224783, Price codes: A04 in paper copy, A01 in microfiche. Technical Report No 24, August 1981. 56 p, 13 Fig, 3 Tab, 87 Ref. OWRT A-018-GUAM(1), 14-34-0001-0112.

Descriptors: *Land clearing, *Guam, *Small watersheds, *Limnology, *Ecological effects, Watersheds, Aquatic environment, Environmental effects, Water quality, Clear-cutting, Soil temperature, Air temperature, Water temperature, Conductivity, Hardness, Hydrogen ion concentration, Phosphorus, Orthophosphates, Runoff.

A study of the limnology and aquatic ecology of a small watershed in southern Guam showed that land-clearing had pronounced effects when compared to that of an upstream control area. While no significant differences were observed in nitrate concentrations and turbidity between stations, significant mean differences were observed in the watershed in soil temperatures (0.7 degrees greater), maximum air and water temperatures (1.4 degrees less), minimum water temperature (2.0 degrees higher), conductivity (11.0 micro-mhos/sq cm less), hardness (9.0 mg/l less), pH (0.22 pH units greater), and in total phosphorus and orthophosphate concentrations (8.15 and 1.64 micrograms/1 less, respectively). Savanna vegetation repopulated the perturbed ravine forest watershed, and thus appeared to be an earlier stage of succession than the ravine forest. Fire or continued clear-cutting would set back succession and maintain savanna vegetation in the watershed. Clear-cutting increases water loss and may accentuate droughts and flooding. In addition, increased temperatures and nutrient losses from the land may cause algal blooms in the downstream areas, and nutrient losses may be long-term problems. (Zielinski-MAXIMA)

LIFE HISTORY AND HABITAT UTILIZATION OF CUTTHROAT TROUT (SALMO CLARKI) IN A HEADWATER STREAM ON THE OLYMPIC PENINSULA, WASHINGTON,
J. A. June.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224817, Price codes: A07 in paper copy, A01 in microfiche. M.S. Thesis, June, 1981. 116 p, 22 Fig, 31 Tab, 95 Ref, 1 Append. OWRT A-101-WASH(1).

Descriptors: *Trout, *Life history studies, Aquatic habitats, Coastal streams, *Land clearing, *Probabilistic process, Fish migration, Growth, Fish populations, Life cycles, Headwaters, Streams, Coastal waters, Canopy, Environmental effects, Probability distribution, Mathematical studies, Model studies, Computer models, *Bear Creek, *Washington, Baseline studies.

A study of the life history and habitat utilization of cutthroat trout in Bear Creek, Washington, provided baseline information for a timber removal study. Trout life history information included upstream adult spawning migration, spawning, incubation and emergence, population dynamics, and movement. Trout habitat utilization study included quantifying the Bear Creek habitat, calculating probability-of-use curves by trout life stage for certain habitat parameters, and combining the two in a habitat utilization model that calculated quality of habitat indexes. The indexes were correlated with biological measurements taken in the same sections. Significant positive correlations were found between the mean length and weight of adult trout and the quality of the indexes. Depth, velocity, and instream cover proved to be the most important of six parameters measured in relation to trout biomass and density. While there were differences in timing of spawning of resident and sea-run cutthroat trout, life history characteristics of both sea-run and resident cutthroat trout in Bear Creek were similar to those reported for other Pacific Northwest streams. The effects of timber canopy removal on density and growth of Bear Creek trout would have to be considerable to be distinguished from the effects caused by variable trout recruitment. SOME FEATURES OF THE TOXIC ACTION OF THE NON-IONIC SURFACTANT LAUROX-9 ON DAPHNIA MAGNA,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
E. P. Shcherban.
Hydrobiological Journal, Vol 16, No 5, p 83-86, 1980. 1 Fig, 1 Tab.

Descriptors: *Surfactants, *Daphnia, *Toxicity, Water pollution effects, Crustaceans, *Laurox-9, Nonionic surfactants, Detergents, Organic compounds, Invertebrates, Eggs, Mortality, Laboratory studies.

The chronic effects of 1, 10, and 25 mg per liter of Laurox-9, a nonionic surfactant, on Daphnia magna were determined for successive generation. The surfactant was toxic to the crustacea at all levels. At the highest level a large proportion of eggs were aborted or the embryos born dead. Many of the live young had morphological defects. The second generation was of low viability, and the third generation failed to reproduce. The 1 mg per liter concentration of Laurox-9 caused a one week reduction in the minimum life span with each successive generation–from 30 days for the first generation to 17 days for the third. Egg abortion in the second and third generations was 5-6 times greater than in the first generation. The second and third generations produced more, but smaller-sized, eggs than the first generation. In the fourth and subsequent generations frequent egg abortion and slow embryo development were evident. Daphnia exposed to the 10 mg per liter concentration of Laurox-9 also had egg abortions, similar in number for the first 3 generations, and nearly doubled for the fourth and fifth generations. A secondary egg batch was often produced. If the interval between batches was 1-1.5 days these secondary eggs developed faster than the first batch. If the interval was 2 days or longer, all undevel-

oped eggs and hatched young were ejected from the brood chamber. Dwarf individuals were often observed. These eventually reached normal size. (Cassar-FRC)

CHANGES IN THE FATNESS OF ROACH (RUTILUS RUTILUS) UNDER THE INFLUENCE OF WARM WASTE WATER FROM A DISTRICT POWER STATION,
Gosudarstvennyi Nauchno-Issledovatelskii Inst. Ozernogo i Rechnogo Rybnogo Khozyaistva, Leningrad (USSR).
V. V. Baranova.
Hydrobiological Journal, Vol 16, No 5, p 61-66, 1980. 1 Tab, 21 Ref.

Descriptors: *Fish, *Thermal pollution, *Lipids, *Roach, Heated water, *Water pollution effects, Seasonal variation, Powerplants, *Ivan'kovo Reservoir, *USSR.

Lipid contents of roach tissues (dorsal muscles, liver, gut, and gonads) were determined in populations exposed to thermal effluent from a power station in Ivan'kovo Reservoir during 1973-75. Water temperature was higher in the thermal discharge region by 11.2C in winter, 7.8C in summer, and 8.8C in autumn. Lipid contents of the tissues followed similar seasonal patterns in both warm water and control groups. The two groups of fish showed no differences in lipid content of muscles (range 2.78-6.55%). However, during summer and autumn the livers, gut, and gonads from the warm water fish were higher in lipid content than organs from the control fish. (Cassar-FRC)

ENZYME ACTIVITY AND KINETICS IN SUBSTRATE-AMENDED RIVER SEDIMENTS,
Sheffield University (England) Dept. of Microbiology.
J. E. Duddridge, and M. Wainwright.
Water Research, Vol 16, No 3, p 329-334, March, 1982. 6 Fig, 5 Tab, 13 Ref.

Descriptors: *Enzymes, *Sediments, Rivers, Sedimention, Mathematical equations, Michaelis-Menten equation, Amylase, Cellulase, Urease, Kinetics, *Heavy metals, *Enviromental effects, *Microbiological studies, England.

This paper reports studies to develop assays to measure amylase, cellulase and urease activity in substrate-amended river sediments, and to determine whether activity follows Michaelis-Menten kinetics. Sediments were sampled from four English rivers. The pH optimum for amylase activity was between 5.9 and 6.2 Linear relationships between amylase activity, length of incubation up to to 8 hr and sediment concentration up to 10 ml were demonstrated. The temperature optimum for amylase activity in all sediments was between 45 and 55 degrees C. Optimum pH for cellulase activity in the sediments ranged from 5.6 to 6.8. In all sediments cellulase activity showed a linear increase time and sediment concentration up to 10 ml. Optimum temperature for activity was between 37 and 44 degrees C, and the enzyme was denatured above 55 degrees C. Optimum pH for urease activity in all four sediments was in the range 7.1-7.4. Linear relationships between urease activity and incubation time up to 8 hr and sediment concentration up to 10 ml were established. Enzyme activity was inherently low in the sediments studied, but increased markedly on the addition of substrate, approximating the situation where starch, cellulase and urea enter the sediments as pollutants or from natural sources. Sediment enzyme activity generally obeyed Michaelis-Menten kinetics, but of the three enzymes, urease gave least significant correlation coefficients when the data for substrate concentration versus activity was applied to the Eadie-Hofstee transformation of the Michaelis-Menten equation. BIOLOGICAL MONITORING, PART IV - TOXICITY TESTING,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
A. L. Buikema, Jr., B. R. Niederlehner, and J. K. Cairns, Jr.
Water Research, Vol 16, No 3, p 239-262, March, 1982. 8 Fig, 2 Tab, 146 Ref.

Descriptors: *Toxicity, *Testing procedures, Monitoring, *Bioindicators, Fish, Reviews, Water quality, Water pollution control, Pollution effects, Aquatic life.

The review describes the most common toxicity tests as they are currently carried out for the purpose of managing pollution in the environment. The type of information provided by each type of test is described, along with various attempts made to apply this information in environmental management schemes. Most toxicity tests have evaluated the short-term lethality of wastes to adult fish. Fish have been the most popular test organism, as they are presumed to be the best understood organism in the aquatic environment and perceived as most valuable by the majority of laymen. Acute toxicity tests are described from the viewpoint of the format of a test, specific considerations in test design, and the use of controls. Data collected from these tests are considered in relation to the response curve, the calculation of the median lethal dose and fiducial limits, comparisons of acute toxicity, and test standardization, Consideration is also given to the sublethal chronic test, deriving safe concentrations, and the application of toxicity test data in environmental management. In spite of increased sophistication in toxicity test methods, increased awareness of the variety of processes operating in a natural system, and the integration of information from a system of tests in various hazard evaluation protocols, the ultimate question of what is an acceptable concentration of a chemical ascertained with a known degree of accuracy is still unanswered. Research is needed on the development and validation of prediction strategies rather than the development of new toxicity tests. (Baker-FRC)
W82-05339

BIOLOGICAL MONITORING. PART V - PREFERENCE AND AVOIDANCE STUDIES,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
D. S. Cherry, and J. Cairns, Jr.
Water Research, Vol 16, No 3, p 263-301, March, 1982. 4 Fig, 7 Tab, 303 Ref.

Descriptors: *Reviews, *Bioindicators, Monitoring, *Temperature effects, Heated water, Plumes, Water quality, Chlorine, Environmental effects.

Preference and avoidance studies can be used to determine if fish or other aquatic organisms that are mobile will avoid plumes of toxic materials, whether a thermal plume or other water discharge causing no adverse biological effects will nevertheless alter the distribution of aquatic life, and whether prior conditions to which organisms have been accustomed tend to alter the preference-avoidance response, and can compare preference and avoidance data of fish to the lethal thresholds of elevated temperature and chemical effluents. Various methodologies are reviewed, including temperature preference studies, chemical avoidance studies, and temperature and chlorine avoidance tests. A ranking of final temperature preferenda by fish families is tabulated, and the relationships, between preference, avoidance, and lethal temperatures are considered. Consideration is also given to the correspondence between behavioral responses in laboratory and field thermal chlorinated effluents. (Baker-FRC)

THE CONTINUING STRUGGLE OF WATERBORNE ILLNESS,
E. W. Taylor.
Aqua, No 1, p 12-14,15, 1982.

Descriptors: *Public health, *Water quality, *Pathogens, Water treatment, *History, *Waterborne diseases, Drinking water, Diseases, Water pollution effects, Bacteria.

A pioneer in the fight against waterborne diseases was a London medical practitioner, Dr. John Snow, who established a connection between cholera epidemics and water supplies in the 1850's, more than 20 years before the discovery of bacteria. Other important investigators in this field were Robert Koch, who identified the causative agent of cholera in 1882, and Percy Franklin, who demonstrated the concept of fecal bacteria as indicators of sewage pollution. Waterborne diseases are still problems in subtropical and tropical areas and among visitors returning from these areas. Cholera, typhoid fever, Salmonellosis, infectious hepatitis, guinea worm, and bilharzia occur to varying degrees in both undeveloped and developed countries. Many types of water treatment are available to combat these diseases. Direct abstraction of river water with chlorination, coagulation, rapid filtration, etc. is less reliable than slower, self-purification methods. Sometimes only a few hours elapse between abstraction and consumption, allowing little time to correct quality problems. Additional disadvantages of abstracting water from rivers are the presence of small aquatic animals and ova in the distribution system and the formation of trihalomethanes from organic matter. The modern view is that water must be safe and attractive to drink (free from visible suspended matter, color, tastes, smells, undesirable bacteria, and all substances hazardous to health) and not corrosive to metals. CHRONIC EFFECTS OF AMMONIA-STRIPPED OIL SHALE RETORT WATER ON FISHES, BIRDS, AND MAMMALS,
Colorado State Univ., Fort Collins. Dept. of Fishery and Wildlife Biology.
R. R. Nystrom, and G. Post.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 3, p 271-276, March, 1982. 2 Tab, 9 Ref.

Descriptors: *Fish, *Wildlife, *Oil shale, *Water pollution effects, Birds, Hamsters, Trout, Fathead minnows, Quail, Ammonia, Industrial wastewater, Mine wastes, Toxicity, Environmental effects, Ecological effects, *Oil shale mining.

The effects of chronic low-level exposure of fish and wildlife to ammonia-stripped oil shale retort water (SRW) were investigated using rainbow trout (Salmo gairdneri Richardson), fathead minnows (Pimephales promelas Rafinesque), coturnix quail (Coturnix coturnix Temminck and Schlegel), and golden hamsters (Mesocricetus auratus Water). Some parameters of SRW were: total Kjeldahl nitrogen, 1180 mg per liter; phenols, 47 mg per liter; conductivity, 13,000 micromhos per cm; and ammonia, 1320 mg per liter. Normal activity, behavior, and appearance continued among all the animals exposed for 10 months to SRW at the following concentrations: trout and fathead minnows, 50 or 100 ppm in water and 10% v/w SRW in food; hamsters and quail, 25% v/v SRW in drinking water and 10% v/w SRW in food. Trout showed mortalities of 85% at the 250 ppm level and 100% at 125 ppm. Examination of liver, kidney, spleen, pancreas, intestine, and other tissues revealed no pathological changes attributed to exposure to SRW. (Cassar-FRC)

KRAFT PULP MILL EFFLUENT COMPONENTS CAUSE LIVER DYSFUNCTION IN TROUT,
Helsinki Univ. (Finland). Dept. of Zoology.
A. O. J. Oikari, and T. Nakari.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 3, p 266-270, March, 1982. 1 Tab, 22 Ref.

Descriptors: *Fish, *Toxicity, *Pulp and paper industry, Bioassay, Water pollution effects, *Trout, Industrial wastewater, Liver, Kraft mills, Sublethal effects.

Studies are underway to devise improved methods of ascertaining sublethal effects of pulp and paper industry discharges on aquatic life. Juvenile rainbow trout, exposed to sublethal concentrations of a

LIBRARY U. OF I., URBANA-CHAMPAIGN

sulfate resin soap, a substance typical of kraft mill effluents, showed evidence of liver function impairment, particularly liver glycogen depletion and UDP-glucuronyltransferase activity. Exposures were 0.3 of the 96 hour LC50 (0.53 mg) for 3 days and 0.15 of the 96 hour LC50 for 11 days. Liver gylcogen was 0.67 + or - 0.31% in the 3 day test and 0.58 + or - 0.34% in the 11 day test, compared with 2.06 + or - 0.54% in the unexposed control fish. Liver UPD-glucuronyltransferase values (in micrograms per g protein) were: control, 223 + or - 18; 3-day test, 160 + or - 19; and 11-day test, 134 + or - 13. There were also significant increases in % of liver somatic index, plasma ammonia, and plasma total bilirubin and a decrease in plasma glucose in fish exposed for 11 days. (Cassar-FRC)

BENTHOS INVESTIGATIONS: SEDIMENT BOXES OR NATURAL BOTTOM,
Texas Univ. at Austin, Port Aransas. Marine Science Inst.
R. W. Flint, T. W. Duke, and R. D. Kalke.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 3, p 257-265, March, 1982. 2 Fig, 1 Tab, 12 Ref.

Descriptors: *Benthic fauna, *Species composition, *Sediments, Invertebrates, Aquatic animals, Bottom sediments, *Estuarine environment, Experimental design.

The differences in benthic community structure between the natural marine bottom and sediment boxes colonized with fauna under both field and laboratory conditions were studied from December 5, 1979, to February 4, 1980. Cluster analysis of species list for the 3 types of samples suggested that laboratory-colonized sediments had a patchier distribution of species than field-colonized sediments or natural estuarine bottom sediments. According to inverse cluster analysis the dominant fauna were similar in all 3 groups. However, the species assemblage of the laboratory-colonized group was otherwise very different from the other 2 groups. Total biomass and density of the dominant organisms, Abra aequalis, per 0.18 sq m sediment box were 25.4 grams and 42,900 individuals (average weight 0.6 mg) in the field-colonized sediments, 2.3 grams and 1461 individuals (average weight 1.6 mg) in the natural bottom sediments, and 3.5 grams and about 1250 individuals in the laboratory colonized sediments. Natural bottom samples had larger individuals than the colonized communities. The large numbers of small Abra aequalis in the field boxes were probably artifacts of the phase of colonization and reproductive cycle. The field-colonized communities would probably stabilize and approach the size and composition of the natural community after a longer period. The field-colonized sediment boxes were a better alternative than laboratory-colonized boxes for studying natural benthic communities. (Cassar-FRC)

THE EFFECT OF PHOSPHORUS LIMITATION ON ALGAL GROWTH RATES: EVIDENCE FROM ALKALINE PHOSPHATASE,
McGill Univ., Montreal (Quebec). Dept. of Biology.
R. E. H. Smith, and J. Kalff.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 11, p 1421-1427, November, 1981. 7 Fig, 1 Tab, 31 Ref.

Descriptors: *Phosphorus, *Algae, *Growth rates, Nutrients, Phosphates, Enzymes, Lake Memphremagog, Eutrophication, Metabolism, *Limiting nutrients, Effects, Indicators, Canada.

Alkaline phosphatase (APA) is an enzyme induced by phosphorus limitation in many phytoplankton species and is quantitatively related to phosphorus-limited growth in some species. Previous studies have shown the APA correlates with other signs of phosphorus shortage in several lakes and have defined APA values characteristic of severe, mild, and no limitation. The development of APA in continuous flow cultures of natural freshwater phytoplankton communities was studied to further quantify phosphorus limitation of phytoplankton growth in situ. Natural phytoplankton communities from oligothrophic-eutrophic Lake Memphremagog were grown at phosphorus-limited rates of 0.06 to 0.03 per day. APA was found to vary inversely with phosphorus-limited growth rate and to be generally uninfluenced by the community composition changes that occurred in culture. The average in situ APA in Lake Memphremagog during the ice-free season was lower than that of cultures and suggested that phosphorus-limited growth rates were greater than 0.6 per day in even the most oligotrophic sections of the lake. Algal abundance varies with total phosphorus in most north-temperate zone lakes, including Lake Memphremagog. However, data from these tests show that average community growth rates are normally high and change relatively little over a fourfold range of total phosphorus concentration. (Carroll-FRC)

FISH ABUNDANCE AND DISTRIBUTION NEAR THREE HEATED EFFLUENTS TO LAKE MICHIGAN,
Argonne National Lab., IL.
S. A. Spigarelli, R. M. Goldstein, W. Prepejchal, and M. M. Thommes.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 39, No 2, p 305-315, February, 1982. 4 Fig, 4 Tab, 14 Ref.

Descriptors: *Thermal pollution, *Nuclear powerplants, *Fish populations, *Ecological effects, Plumes, Lakes, Water pollution effects, Heated water, Powerplants, Electric powerplants, Environmental effects, Seasonal variation, Thermal water, Water temperature, Effluents, *Lake Michigan.

The abundance and distribution of fish with depth and temperature in locally heated and unheated sections of Lake Michigan were examined by a combined echo location-temperature mapping procedure. Measurements were taken between April and October at two adjacent powerplants in the southern basin and at one plant in the northern basin. Seasonal variations in fish densities were found in both plume and reference areas. The greatest plume densities were recorded in late spring, when alewife were spawning inshore. High fish densities were consistently noted downstream of the interfaces between ambient shore-parallel currents and discharge flows. At canal discharges, fish tended to congregate inshore, while at the offshore discharge, they congregated in deeper zones. In plume areas, fish tended to occupy shallower depth strata, which were 1-3 degrees higher than the maximum ambient temperatures. A positive correlation between fish density and increasing temperature was generally observed at both plume and reference stations during all three seasons studied. (Geiger-FRC)

Descriptors: *Fish, *Wastewater, *Metabolism, Water pollution effects, *Trout, Enzymes, Liver, Steroids, Polyaromatic hydrocarbons, Oil pollution, Organic compounds, Mixed function oxidase, *Bioassay, Laboratory studies, *Treated municipal wastewater.

The effects of treated municipal wastewater on liver microsomal in vitro metabolism of 4-androstene-3,17-dione, benzo(a) pyrene, ethylmorphine, and p-nitroanisole were studied in rainbow trout (Salmo gairdneri). Fish were exposed for 2 weeks to two effluent: tap water ratios, 1:5 (Group B) and 1:1 (Group C). Group B fish showed significant increases in NADPH cytochrome c reductase on a liver weight basis. Group C showed significant increases in cytochrome P-450, NADPH cytochrome c reductase, and microsomal protein on a liver weight basis, but not on a protein weight basis, and an increase in liver somatic index. In vitro incubation of liver tissue from effluent-exposed fish with benzo(a)pyrene, ethylmorphine, and p-nitro-anisole produced increases in p-nitroanisole o-demethylase and benzopyrene hydroxylase activities and decreases in ethylmorphine N-demethylase activity. Fish exposed to effluent showed altered liver microsomal metabolism of androstenedione; 6-beta-hydroxylase activity was decreased, 17-hydroxysteriod oxidoreductase activity was increased, and 5-alpha reductase activity was not changed. Although the in vivo effects cannot be predicted, it is possible that production of mutagens and carcinogens may be increased and distrubances in the endocrine system may occur. (Cassar-FRC)

Water, Air, and Soil Pollution, Vol 17, No 1, p 17-28, 1982. 8 Fig, 3 Tab, 29 Ref.

Descriptors: *Fluorides, *Human diseases, *Water quality, Cancer, Chemical composition, Environmental effects, Sri Lanka, Geography, Well water, Geochemistry.

The incidence of dental disease and the distribution of fluoride in drinking water wells in Sri Lanka was investigated. Dental fluorosis and caries and the total incidence of cancer were studied. Fluoride ions were measured with the Orion ion specific electrode. The central hill country and the southwest coastal regions were relatively free of fluoride. The lowland dry zone contained a higher amount of fluoride in the water, with areas around Eppawala in the North Central Province, Maha Oya in the Eastern Province and Uda Walawe in the Southern Province showing anomalously high fluoride concentrations. Areas of high fluoride content showed a higher dental fluorosis, whereas individuals living in low fluoride regions suffered from dental caries. The intensity of rainfall is a major factor in the geographical distribution of fluoride in well water, but the natural geological factors are also significant. A proportional increase of fluoride with water hardness was noted, reflecting the geochemical status of ions in the rocks and minerals of the area. In studying the variation of the total cancer rates with the total dissolved solids in the water and the hardness of the water in the nine provinces of Sri Lanka, it became apparent that even though the curves for total solids and hardness against cancer incidence appear to be complementary, the relationship is not a simple one and there is an optimum level of hardness and total solids that corresponds to a minimum incidence of cancer. The complementary association of environmental factors such as rainfall, dissolved ions and water hardness with the incidence of cancer points to the use of goechemical correlative factors as a guide in the delineation of disease areas. INVESTIGATIONS INTO THE PROTECTIVE EFFECT OF ESTUARINE SEDIMENT ON VIRUS SURVIVAL,
Baylor Coll. of Medicine, Houston, TX. Dept. of Virology and Epidemiology.
R. LaBelle, and C. P. Gerba.
Water Research, Vol 16, No 4, p 469-478, April, 1982. 7 Fig, 3 Tab, 38 Ref.

Descriptors: *Coastal waters, *Enteroviruses, *Adsorption, *Marine sediments, *Fate of pollut-

ants, *Water pollution sources, Bacteria, Bacteriophage, Bioindicators, Estuaries, Biological magnification, Viruses, Sediments, Pathogens.

Contamination of coastal waters with human pathogens can lead to the elimination of these resources from human use. Viruses can be bioaccumulated in filter-feeding shellfish and cause epidemics of hepatitis and gastrointestinal diseases. The adsorption of enteric viruses to estuarine sediments helps to prolong their survival in marine waters. Studies were carried out to ascertain whether sediment protects viruses from any one specific inactivating factor. The properties of sediment responsible for such protection were also investigated. Laboratory tests showed that sediment protected poliovirus 1 (strain LSc) from inactivation by microorganisms, salts, and heat. Anaerobic conditions did not affect virus survival. Bacteria nutrients increased virus survival, probably by enhancing the number of bacteria available for virus adsorption. The presence of natural organic matter did not enhance virus survival in sea-water. (Geiger-FRC)

RELATIONSHIP BETWEEN THE DISTRIBUTION OF PHOSPHORUS COMPOUNDS IN THE TISSUES OF THE BIVALVE ANODONTA CYGNEA AND ENVIRONMENTAL PHOSPHORUS LEVEL,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
V. D. Solomatina.
Hydrobiological Journal, Vol 17, No 1, p 54-59, 1981. 1 Fig, 3 Tab, 17 Ref.

Descriptors: *Phosphorus, *Aquatic environment, Chemical reactions, Environment, Mollusks, Water pollution effects, Metabolism.

The effect of an increased level of inorganic phosphorus in water on some of the indices of phosphorus metabolism in bivalve tissues was investigated. Experiments were conducted in aquaria on tissues of the bivalve Anodonta cygnea. Phosphorus content in the control aquarium was 0.06 mg/liter. An increased phosphorus concentration in the experimental aquaria was created by adding suitable amounts of disodium phosphate. The experiments showed that an increase in the lovel of phosphorus in the water appreciably influenced its entry into the organism of the mollusks and its distribution therein. A typical tissue reaction of their glandular organs to an increase of phosphates in the water was established. Total phosphorus in the mantle of the mollusks was appreciably increased from the third day of the research, when there was 0.3 mg/liter of phosphorus in the medium. The rate of total phosphorus accululation in the mantle increased with the time spent by the mollusks in such a medium. When phosphate content in the water was increased to 0.6 mg/liter, the amount of total phosphorus in the mantle began to increase on the very first day under these conditions. An increase of organic phosphorus content in the water to an amount 5-10 times its content in natural water has an appreciable effect on the trend of bioenergetic processes in the tissues of the mollusks. This effect was most marked in the mantle. Under the influence of increased phosphorus content in the environment of the fresh water mollusks appreciable changes were noted in the enzyme activity, the nature of which was dependent on the phosphorus level in the water. CHOLINESTERASE ACTIVITY IN ESTUARINE FISHES IN THE CUMULATION OF DDT,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii
O. V. Maslova.
Hydrobiological Journal, Vol 17, No 1, p 69-72, 1981. 1 Fig, 5 Ref.

Descriptors: *Fish populations, *Water pollution effects, Pesticide toxicity, Toxicity, Rivers, Cholinesterase, Enzymes, Accumulation, Bioaccumulation.

The level of concentration of DDT and its metabolites DDD and DDE was investigated in the organs and tissues of fishes from the Danube and the Dnieper, and the functional shifts occurring during chronic intoxication by sublethal DDT concentrations were analyzed. Fish were caught during the summer months of 1978 and 1979. The indices of cholinesterase activity in the liver and brain tissues of the fishes from the Dnieper-Bug estuary were generally higher than those in fishes from the Danube delta containing large residual amounts of DDT. Cholinesterase activity of liver tissues of pike-perch yearlings from the Danube delta was significantly lower (by 36%) than activity in pike-perch yearlings from the Dnieper-Bug estuary. As regards cholinesterase activity in the blood of the fishes studied, the results indicate that this characteristic either fails to react to the presence of DDT in the fish organism, or is increased in relation to the increase in the concentration of the toxicant. Species differences in cholinesterase activity were noted. Significant age-related differences were also found in the cholinesterase activity of the organs of the fish, and also in DDT concentrations. In all the species investigated it was the brain that had the greatest cholinesterase activity, that of the liver was less, and that of the blood least. When this characteristic was compared in fishes of different trophic levels, it was noted that the cholinesterase activity of the organs and the blood of nonpredatory fishes form the two water bodies differed less than in predatory fishes. The accumulation of residual amounts of DDT and the associated reduction of cholinesterase activity are indications of possible functional disturbances to the nervous system and to metabolic processes, and overall of a reduction in the resistance of the organism to the effect of adverse environmental factors. BIOLOGICAL RESPONSES ON LAKES IN THE MOUNT ST. HELENS BLAST ZONE,
Washington Univ., Seattle. Fisheries Research Inst.
R. C. Wissmar, A. H. Devol, J. T. Staley, and J. R. Sedell.
Science, Vol 216, No 4542, p 178-181, April 9, 1982. 1 Fig, 2 Tab, 20 Ref.

Descriptors: *Lakes, *Volcanoes, *Aquatic life, Mount St. Helens, Organic matter, Air pollution, Water pollution effects, Ecological effects, Phytoplankton, Algae, Adenosine triphosphate, Bacteria, Chlorophyll a, Nutrients, Light penetration.

The biological effects in lakes impacted by the May 18, 1980, eruption of Mount St. Helens, Washington, were investigated on June 30, 1980. In Spirit Lake suspended particulate matter increased 33-fold; light extinction coefficient, 36-fold; dissolved organic matter, 48-fold; and adenosine triphosphate, 17-fold. Other lakes within the blast zone showed increases in these parameters to a varying degree. Total bacterial counts were above 1 million per ml compared with 0.1 to 0.8 million per ml in unaffected lakes. Viable bacteria were 0.02-3% of total bacteria. Total and fecal coliforms were as high as 10,000 per 100 ml in some lakes. The high levels of dissolved organic carbon, product of pyrolyzed and steam-leached vegetation and soils, provided a food source for the bacterial population. Algal concentrations were very low, most likely as a result of light limitation rather than toxicity or competition for nutrients. The biological life of the lakes may not recover until significant mineral alterations, organic degradation, and vegetation regrowth occur. (Cassar-FRC)

THE IMPACT OF ACIDIC PRECIPITATION AND HEAVY METALS ON SOILS IN RELATION TO FOREST ECOSYSTEMS,
Maine Univ. at Orono. Dept. of Geological Sciences.
S. A. Norton, D. W. Hanson, and R. J. Campana.
In: Proceedings of Symposium on Effects of air Pollutants on Mediterranean and Temperate Forest Ecosystems, June, 1980, Riverside, California. Report PSW-43, Forest Service, USDA, Berkeley, California. p 152-157, 3 Fig, 1 Tab, 23 Ref. OWRT A-026-ME(9), 14-31-001-4240.

Descriptors: *Acid rain, *Fallout, *Air pollution effects, *Heavy metals, *Water pollution effects, Rainfall, Air pollution, Acidic water, Accidity, Environmental effects, Water pollution effects, Pollution load, Lead, Leading, Hydrogen ion concentration, Sulfuric acid, Vegetation effects.

Acid precipitation, experimentally and empirically, accelerates podsolization and depletes nutrient pools in forest litter and shallow inorganic soils. Further, normal terrestrial cycling of metals in eastern North America and the Pacific coast States has been altered by increasing precipitation acidity. Some heavy metals (e.g., lead) accumulate to concentrations which may impede biological soil processes and inherit phosphorus (P). Other metals are being leached from soils and inherit phosphorus (P). Other metals are being leached from soils (Al, Ca, K, Mg, and Mn). It was observed that the mobilities of Fe, Zn, and P vary with site characteristics. Biological recycling of nutrients by decomposition and uptake is impeded by a lowered pH and elevated levels of toxic metals in soils. Increased nutrient leaching caused by increased hydrogen ion input, decreases the percent base saturation. Deeper rooted plants are subjected to elvated (potentially toxic) concentrations of dissolved metals (e.g., Al and Mn). The results of this work indicates that nutrient pools are decreasing in the northeast U.S., suggesting that decreases in forest productivity will occur. (Zielinski-MAXIMA)

A summary of the streamside timber removal study conducted at Bear Creek is presented. In this study, the components of the stream ecosystem influenced by removal of riparian vegetation were isolated from physical disturbances (road building and log yarding) by postponing removal of fallen timber in a streamside management zone (SMZ), and by delaying watershed logging. Physical and biological parameters linked with cutthroat trout production were examined for two years (1977-78) in designated treatment and control zones. Commercially-valued timber was then carefully removed from the tratment zone in a way that assured maintenance of under-story vegetation and streambank integrity. Keg environmental parameters in the post-treatment (1979-80) and pre-treatment (1977-78) phase were intercompared. It was deduced that canopy density reduction causes quantity and quality changes for fixed energy inputs entering the stream, and stimulates can increase in the density and biomass of the fish food supply. Sclimonid biomass can be controlled by fish food availability; hence canopy density is functionally related to fish production through a food supply control mechanism. Further, riparian management is functionally related to fish population density and age structure. Proper implementation of the SMZ concept affords a useful management practice. (Zielinski-MAXIMA)

CLASSIFICATION AND MANAGEMENT OF WETLANDS IN THE WESTERN KENTUCKY COAL FIELD,
Kentucky University, Lexington Water Resources Research Inst., KY.
W. J. Mitsch, and R. W. Bosserman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236639, Price codes: A05 in paper copy, A01 in microfiche. Report 131, March, 1982. 78 p, 25 Fig, 15 Tab, 66 Ref. OWRT A-086-KY(1), 14-34-0001-1119.

Descriptors: *Wetlands, *Coal mining, *Management planning, *Field tests, *Model studies, Coal mines, Strip mines, Assessments, On-site tests, Sites, Water quality, Ecological distribution, Computer models, Watersheds, Ecosystems, Mine drainage, Classification.

This initial research report of a three-year study on wetland identification and management criteria in the western Kentucky coal field focuses on four specific activities: establishment of three intensive study sites in major wetlands for identification and management impact assessment; sampling the study site to measure water quality and ecologic structure; application of a developed classification to the study sites; and development of conceptual models of the region, watersheds, and specific ecosystems, and preliminary simulations of a wetland model. The study sites are affected by mine drainage, channelization, higher water levels, oil wells, and agriculture clearing. Preliminary analysis of field surveys demonstrated that coal mining and oil extraction may affect wetlands health; drainage, logging, channelization, and impoundments have also caused significant alterations. Field measurements and conceptual models facilitated classification scheme development for the wetlands, which considers ecologic structure system hydrology, and major man-made effects. A number of water quality (e.g., pH, temperature, conductance, sulfates, turbidity) and ecologic (e.g., vegetation growth, biomass) parameters will be considered for impact assessment relative to standard values. OIL AND GREASE IN STORMWATER RUNOFF,
California Univ., Los Angeles. Dept. of Engineering Systems.
M. K. Stenstrom, G. Silverman, T. A.
Bursztynsky, A. L. Zarzana, and S. E. Salarz.
Report, February 1982. Association of Bay Area Governments, Berkeley, California. 241 p, 41 Fig, 44 Tab, 158 Ref, 3 Append.

Descriptors: Storm water, *Storm runoff, *Urban runoff, *Oily water, *Grease, Sampling, Land use, Hydrocarbons, Chromatography, Wastewater, Oil pollution, Runoff rates, Adsorption, Rainfall-runoff relationships, Environmental effects, Path of pollutants, *San Francisco Bay, Ecological effects.

The objective of this project was to determine the environmental effects of oil and grease in urban stormwater on marine environments in San Francisco Bay and to recommend suitable control measures. Studies show that there are significant effects of low level oil/grease pollution and that continuous pollution from urban stormwater can change the ecology of a marine environment. Five field sampling stations were selected in a stormwater basis in Richmond, CA to determine oil/grease pollution by land-use type. Samples were taken from the mouth of the watershed, a parking lot, a commercial street, a residential area, and from a light industrial facility. Land-use strongly affects oil/grease in stormwater. The major contributing factor is motor vehicles. Areas with the most auto traffic had the highest concentration of oil/grease in stormwater and the highest hydrocarbon load factor. Mean oil/grease concentration in runoff flow ranged from 4.13 mg/1 in an upstream residential area to 15.25 mg/1 in a parking lot. A strong correlation exists between total rainfall and total mass of oil/grease pollution---contamination is higher at the beginning of a storm than at the end. Nine control techniques showed promise. Three non-structural techniques were to recycle used crankcase oil, reduce auto emissions through better inspections, and improve standards. Six structural techniques were to improve street/parking lot cleaning, sorption systems for manhole and gutter intakes, porous pavement, greenbelts around parking lots, dispersion devices, and wetlands or marshes to trap pollutants. These are site-specific techniques but it was recommended they be developed further. (Atkins-Omniplan)

STRUCTURAL DAMAGE TO LEAF CHLOROPLASTS OF ELODEA DENSA CAUSED BY METHYLMERCURY ACCUMULATED FROM WATER,
National Research Council of Canada, Ottawa (Ontario). Div. of Biological Sciences.
D. C. Mortimer, and M. Czuba.
Ecotoxicology and Environmental Safety, Vol 6, No 2, p 193-195, 1982. 3 Fig, 4 Ref.

Descriptors: *Plant pathology, *Laboratory studies, *Organic compounds, Methylmercury, Pesticides, Water pollution effects, Industrial wastes, Environmental effects, Rivers, Ottawa, Canada, Elodea densa, Aquatic plants.

One of the effects resulting from the adbsorption of methylmercury by Elodea densa leaves is damage to chloroplast integrity. Elodea densa plants were placed in aquaria with Ottawa municipal water flowing through. Methylmercury solutions of varying strengths were added. The first stage of damage shows swollen chloroplasts with evidence of outer membrane rupture and a suggestion of internal thykaloid disturbance. The micochondria and other organelles appear intact. Second stage revealed exploded or peeled chloroplasts with the outer membrane completely gone. While the mechanism of methylmercury toxicity in the leaves is not yet understood, it is clear that individual cells have different sensitivities to methyl-mercury and that the chloroplast membrane is much more senitive than other membranes within the cell, such as mitochondrial membranes. The tissue level of methylmercury at this stage of damage was about 5 ng/g fresh weight, obtained by absorption from water containing 150 ng/liter over 25 days. With such low concentrations within the plant tissue as a whole, it has not been decided whether the chloroplast membrane is damaged by methylmercury effects acting from within the chloroplast or from the cytoplasmic side of the membrane. EFFECT OF PHENOL ON IN VIVO ACTIVITY OF TISSUE TRANSAMINASES IN THE FISH NOTOPTERUS NOTOPTERUS,
D. A. V. Coll., Muzaffarnagar (India). Dept. of Zoology.
S. R. Verma, S. Rani, and R. C. Dalela.
Ecotoxicology and Environmental Safety, Vol 6, No 2, p 171-176, 1982. 2 Tab, 25 Ref.

Descriptors: *Fish populations, *Phenols, Organic compounds, Water pollution effects, Population exposure, Enzymes, Amino acids.

This study was undertaken to investigate in vivo the chronic effects of the water-pollutant phenol on glutamic oxalacetic transaminase (GOT) and glutamic pyruvic transaminase (GPT) activity in tissues of N. notopterus. Active and healthy fish specimens were collected from freshwater resources. Groups of fish were exposed to concentrations of phenol in tap water equivalent to 1/2, 1/5, and 1/10 of the 96 hr median lethal dose. Fish were examined after 10, 20 and 30 days of exposure. Alterations were produced in activity of the transmaminases in different tissues, and the difference between control and treated fish was significant. In general, the maximum stimulation of GOT was noted in the liver. For GPT maximum stimulation occurred in the heart, reaching the highest concentration after 30 days of exposure. Minimum stimulation for both GOT and GPT was in the kidney, with the lowest concentration occurring after 10 days of exposure. The stimulation pattern was similar in most cases and was found to be dose and duration dependent. The marked stimulation of GOT and GPT activity by phenol suggests a potential for phenol to interfere with processes related to amino acid metabolism inside the fish body. (Baker-FRC)

FLOODWATER NUTRIENT PROCESSING IN A LOUISIANA SWAMP FOREST RECEIVING AGRICULTURAL RUNOFF,
Louisiana State Univ., Baton Rouge. Center for Wetlands Resources.
G. P. Kemp, and J. W. Day, Jr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-243304, Price codes: A05 in paper copy, A01 in microfiche. Final Report, December, 1981. 72 p, 18 Fig, 9 Tab, 85 Ref. OWRT A-043-LA(2).

Descriptors: *Louisiana, *Swamp forest, *Agricultural runoff, Overland flow, *Nutrient dynamics, Eutrophication, Nitrogen, Phosphorus, Hydrologic budget, Decomposing organic matter, Dissolved oxygen, Swamps.

From September 1978 through June 1979, experiments were carried out to: (1) measure N and P dynamics in a Louisiana swamp which receives agricultural runoff, (2) Calculate N and P budgets to determine if there was a net uptake or release, (3) Conduct laboratory experiments to determine the influence of leaf litter decomposition and dissolved oxygen nutrient retention by the swamp. A water budget was calculated as follows: input was 23% precipitation and 77% pumpage, outflows were 11% evapotranspiration and 89% drain. This water budget along with measured nutrient concenrations were used to calculate N and P budgets. Most of the input to the swamp study site (70% N, 74% P) was pumped into the ponds as particulates. Of the total inputs only 3% N and 1% P was introduced with precipitation, however, rain accounted for 30% of the input of total inorganic N. Outflows from the swamp were 56% and 60% of total N and P inputs, respectively. Thus the swamp retained 44% N and 40% P. Most of this was in the form of particulates. The swamp removed inorganic N and exports PO4 and organic N. This is reflected in the characteristically low N:P ratio of the swamp waters. The microcosm studies indicate that dissolved oxygen concentrations are most important factor regulating swamp water chemistry. The results indicate that the swamp can serve as long-term sink for significant quantities of N and P and that burial in sediments and dentrification are mechanisms for permanent losses. HISTOPATHOLOGICAL CHANGES IN THE LIVER AND BRAIN OF FISH EXPOSED TO ENDOSULFAN INSECTICIDE DURING TSETSE FLY CONTROL OPERATIONS IN BOTSWANA,
Centre for Overseas Pest Research, London (England).
P. Matthiessen, and R. J. Roberts.
Journal of Fish Diseases, Vol 5, No 2, p 153-159, 1982. 4 Fig, 2 Tab, 11 Ref.

Descriptors: *Fish populations, *Insecticides *Endosulfan, *Botswana, Fish toxins, Pesticides, Sprays, Spraying, Water pollution sources, Tsetse fly control.

This study was made to determine whether the tsetse control campaign in the Okavango Delta produced significant histopathological changes in exposed fish, and if so, how quickly they recovered after spraying. Studies were confined to liver and brain. Several herbivorous and carnivorous species were investigated, but detailed discussion was limited to Clarias gariepinus and Tilapia rendalli. The histopathological changes were placed in the context of simultaneous observations that were

being made of fish activity and reproductive behavior. Samples were gathered throughout the 1978 spraying season and during the ensuing 7 months. All sampled fish were apparently healthy, and none were taken from locations where fish kills were noted. All species studied contained histological lesions during the spraying season which were distinguishable from the normal background disease pattern and indicative of pesticide induced damage. Lesions in the piscivore Hepsetus odoe were relatively mild, whereas those in the omnivorous Clarias gariepinus and herbivorous Tilapia rendalli were more serious. There is little doubt that the pathological changes were caused by endosulfan. Liver damage in C. gariepinus was severe, especially in the peribiliary tissue. Accumulations of large amounts of lipid were noted in poisoned tissue, and a disappearance of melanomacrophage centers from C. gariepinus liver was observed Pathological changes in T. rendalli brain clearly show that endosulfan has neurotoxic effects. PRELIMINARY INVESTIGATION OF THE ALGAL FLORA IN THE SEDIMENTS OF LAKE ERIE,
State Univ., of New York Coll. at Buffalo. Great Lakes Lab.
V. R. Frederick.
Journal of Great Lakes Research, Vol 7, No 4, p 404-408, 1981. 4 Fig, 2 Tab, 20 Ref.

Descriptors: *Sediments, *Algal growth, Eutrophication, *Lake Erie, Great Lakes, *Diatoms, *Lake sediments.

A preliminary examination was performed regarding the extent of the diatom floras in the sediments of Lake Erie and their applicability in providing a better understanding of the process of natural and cultural eutrophication in the Great Lakes. The non-diatom algal flora in the sediments was also investigated. A 45-cm long core was obtained from a site in the eastern basin of Lake Erie. Asterionella formosa, Melosira islandica, M. italica, Stephanodiscus niagarae, and Tabellaria fenestrata were the most abundant diatoms encountered in the core sample. Thirteen non-diatom algal taxa were identified in the 13 sediment samples. Forty diatom taxa were identified in the sediments of this study. Centric and araphidinate diatoms dominated the flora at all sediment levels. Quantitative diatom profiles and relative abundance profiles each provide a contrasting history of post settlement Lake Erie. In view of the known history of the lake, the relative frequency profiles appear to be most applicable. The C/P index of trophic status and the diatom diversity support those profile. (BAker-FRC)

WATER TEMPERATURES IN NANTICOKE-LONG POINT BAY REGION OF LAKE ERIE,
Ontario Hydro, Toronto. Hydraulic Studies and Development Dept.
R. S. Arden, and R. Farooqui.
Journal of Great Lakes Research, Vol 7, No 4, p 337-344, 1981. 6 Fig, 3 Tab, 5 Ref.

Descriptors: *Water temperature, *Electric power industry, *Lake Erie, Lakes, *Thermal pollution, Heated water, Thermal powerplants, Thermal power.

A summary of continuous temperature data and an analysis of results obtained from temperature measurements taken near the Nanticoke Thermal Generating Station during May to November of 1970-1979 are presented. Although temperatures varied from year to year, generally similar temperatures were recorded at all shore-based stations, with slightly higher temperatures being recorded at Peacock Point during both pre-operational and post-operational years of the power plant. The monthly mean water temperatures at 2 meter depths were generally in step with the air temperature. During the spring, water temperature did not keep pace with changes in air temperature, sometimes varying by as much as 8-10 degrees C. Maximum monthly and daily mean temperatures recorded a the tower location in the Outfall Bay were about 1 degree higher than the nearshore locations during the summer months of 1975 and 1976. This may be attributed in part to the influence of the thermal effluent from Nanticoke GS, as the average plant output for July to September was highest during those years. During the summer and fall large water temperature changes occurred in the Nanticoke-Long Point Bay Region in both pre-operational and post-operational phases of the Nanticoke Generating Station. With the exception of the Outfall Bay location, which had slightly elevated temperatures during 1975 and 1976, the operation of the Nanticoke Generating Station had essentially no effect on the temperature regime of this area. MODELING OF PHYTOPLANKTON-NUTRIENT DYNAMICS IN SAGINAW BAY, LAKE HURON,
Environmental Protection Agency, Grosse Ile, MI. Large Lakes Research Station.
V. J. Bierman, and D. M. Dolan.
Journal of Great Lakes Research, Vol 7, No 4, p 409-439, 1981. 15 Fig, 6 Tab, 48 Ref.

Descriptors: *Phytoplankton, Nutrients, *Lake Huron, *Saginaw Bay, Lakes, *Nutrient dynamics, Great Lakes, Model studies, Phosphorus, Silicon, Plankton, Nitrogen.

A study was conducted to gain insight into the physical, chemical, and biological processes affecting phytoplankton growth and to use the model as a tool for comparing future effects of various waste water management strategies. The multi-class phytoplankton simulation model was set to field data acquired on Saginaw Bay, Lake Huron, during 1974. The concept of a single limiting factor for phytoplankton growth was found to be overly simplistic. Results indicated that temperature and light were relatively more growth rate limiting than nutrients on an annual average bases. However, as a consequence of nutrient depletion, nutrients became relatively more important at the times of peak phytoplankton crops. Nitrogen was more growth rate limiting than phosphorus to the total phytoplankton crop, although important differences occurred among the individual functional groups. While nitrogen and silicon were important in phytoplankton-nutrient dynamics, the supply of phosphorus would ultimately determine the size of the blue-green component of the total crop because nitrogen fixing blue-greens did not have absolute requirements for dissolved available nitrogen or silicon. Phosphorus requirements for summer crops were satisfied by recycle processes within the water column. Phytoplankton production was extremely sensitive to variation in the light extinction coefficient in the water column and relatively insensitive to variations in incident solar radiation. (Baker-FRC)

Journal of the Air Pollution Control Association, Vol 32, No 1, p 79-82, January, 1982. 1 Tab, 14 Ref.

Descriptors: *Waste disposal, *Air pollution, Organic compounds, Hazardous wastes, Environmental effects, Air pollution effects, Volatility, Lagoons, Wastewater lagoons, Ponds.

A method is described for the estimation of organic compound emissions from waste lagoons. The method is based on the best information currently available and offers a simple technique for estimating the volatilization rate of volatile organics from these lagoons. The volatilization rates depend on meteorological conditions occurring at the gas-liquid interface, which may vary appreciably with time. Thus only short-term emission rates can be used for estimation. The rates are also greatly influenced by the presence of surface materials such as floating solids and/or liquids. Based on the illustrative examples given and other calculations, it appears logical to conclude that for most air contaminants of environmental concern, the liquid phase mass transfer coefficient controls the rate of volatile organic compound emissions from waste lagoons, and the gas phase mass transfer coefficient has insignificant effects on the calculation of the overall mass transfer coefficient. The gas phase mass transfer coefficient can be influenced greatly by turbulence and surface films; these effects are not included in the equations. The method as presented becomes fairly simple and straightforward, but it should be used with care and discretion and with a good knowledge of the waste composition and the prevailing physical situation of the waste lagoon. EFFECTS OF SELECTED ORGANIC COMPOUNDS ON RADIONUCLIDE ADSORPTION TO SEDIMENTS IN FRESHWATER SYSTEMS,
Washington Univ., Seattle. Coll. of Ocean and Fisheries Sciences.
J. R. Clayton, Jr., T. H. Sibley, and W. R. Schell.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 409-415, 1982. 1 Fig, 2 Tab, 6 Ref.

Descriptors: *Radioisotopes, *Adsorption, *Sediments, *Organic compounds, Fate of pollutants, Cobalt radioisotopies, Americium radioisotopes, Rubidium radioisotopes, Cesium radioisotopes, Salicylic acid, Acetic acid, Ethylenediamine tetraacetic acid, Phenanthroline, Nitrosonaphthol.

The effects of organic compounds on radionuclide adsorption to sediments were determined using autoclaved sediments and water from Lake Washington, Washington, and Cattaraugus Creek, New York. Organic compounds, selected for the variety of functional groups available for reaction with radionuclides and sediment particles, were 1,10-phenanthroline, acetic acid, salicylic acid, and ethylenediamine-tetraacetic acid (EDTA) all at concentrations of 0.0001 M, and 1-nitroso-2-naphthol at a concentration of 0.00001M. The radionuclides were Co57, Ru106, Cs137, and Am241. Distribution coefficients (kd) were constant with increasing concentrations of EDTA for Ru106 or Cs137. However, for Am241 marked decreases in distribution coefficients occurred at EDTA concentrations of 0.0001 to 0.000001M, a result of the formation of soluble EDTA-Am241 complexes. Statistically significant differences were obtained for Kd values and Am241, Co57, and Ru106 but not for Cs137. Co57 and Am241 Kd were much higher with acetic acid, and lower for EDTA. For Ru106, 1-nitroso-2-naphthol,1,10-phenanthroline, acetic acid, and EDTA all produced higher Kd values than controls, Salicylic acid did not significantly change Kd values for any of the radionuclides tested. The complex variety of interacting factors shows the necessity of characterizing water and sediment chemical parameters in adsorption studies. (Cassar-FRC)

MUTAGENIC POTENTIAL OF WATER CONCENTRATES FROM THE EFFLUENT OF A WASTE OIL STORAGE POND,
Texas A and M Univ., College Station. Dept. of Soil and Crop Science.
K. W. Brown, and K. C. Donnelly.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 424-429, 1982. 1 Fig, 2 Tab, 7 Ref.

Descriptors: *Mutagens, *Oil wastes, *Chlorinated hydrocarbons, Water pollution effects, Carcinogens, Pesticides, Polychlorinated biphenyls, Hexachlorobenzene, Indicators, Bioindicators, Bioassay.

LIBRARY U. OF I., URBANA-CHAMPAIGN

Water samples collected before and after dredging a waste oil storage pond were analyzed by two systems capable of detecting mutagens and carcinogens: the Ames Salmonella/microsome assay and the Bacillus subtilis DNA repair assay. In the Salmonella test bactericidal effects on all strains were observed at doses equivalent to 140 ml of unconcentrated effluent. Although the post-dredging sample produced slight increases in the mutation frequency of strain TA98 at lower dose levels, there was no dose response effect. The pre-dredging sample results were inconclusive. The DNA repair assay showed the presence of DNA damaging agents at a dose equivalent to 400 ml per plate in pre-dredging samples. In the post-dredging sample there was a substantial reduction in capacity to produce repairable DNA damage. Chemical analysis of the oil waste water determined that hexachlorobenzene and polychlorinated biphenyls were present at trace levels in the pre-dredging samples but were undetectable in the post-dredging sample. A SENSITIVITY AND ERROR ANALYSIS FRAMEWORK FOR LAKE EUTROPHICATION MODELING,
W. W. Walker.
Water Resources Bulletin, Vol 18, No 1, p 53-60, February, 1982. 4 Fig, 4 Tab, 21 Ref.

Descriptors: *Eutrophication, *Lakes, *Mathematical models, Water quality, *Error analysis, *Sensitivity analysis, *Simulation analysis, Watersheds, Phosphorus, Chlorophyll A, Watershed protection, Water quality management, Lake Morey, *Vermont, Monte Carlo method.

Agencies responsible for managing lake water quality at regional levels are frequently confronted with a scarcity of information. Data limitations result in uncertainties with respect to assessment of problem conditions and priorities for further study and/or restoration. A modeling framework which permits quantitative assessment of this uncertainty in a useful and flexible manner is described and demonstrated. The Lake Eutrophication Analysis Procedure consists of a series of linked models which predict lake water quality conditions as a function of watershed land use, hydrologic variables, and morphometric variables. Sensitivity and error analysis techniques are presented which provide the user of the model or of a given model linkage with the following statistics for each predicted variable: mean, variance, confidence limits, and ranking of input variables with respect to sensitivity and contribution to prediction variance. Predicted distributions were found to compare favorably with those estimated using Mone Carlo simulation. Application of the framework to data from Lake Morey, Vermont, showed that prediction variances, attributed largely to model error, were comparable to the observed year-to-year variance in water quality, as measured by spring phosphorus concentration, hypolimnetic oxygen depletion rate, summer chlorophyll-a, and summer transparency for this lake. Use of the framework provides perspective on key assumptions and controlling factors and identifies the major sources of uncertainty in a given model application. As a result, it is possible to design effective additional monitoring and/or modelling efforts, and the probability that a significant management decision will be made with excessive confidence in the predicted outcome is reduced. PHYTOPLANKTON RESPONSES TO GROUND WATER ADDITION IN CENTRAL FLORIDA LAKES,
Southwest Florida Water Management District, Brooksville.
P. M. Dooris, G. M. Dooris, and D. F. Martin.
Water Resources Bulletin, Vol 18, No 2, p 335-337, April, 1982. 1 Fig, 1 Tab, 9 Ref.

Descriptors: *Phytoplankton, *Bicarbonates, *Species diversity, Lakes, Water quality, Florida, Inorganic carbon, Carbon, Floridan aquifer, Pumping, Groundwater.

Phytoplankton diversity indexes were higher (especially in the wet season) in small Florida lakes augmented by groundwater pumping than in unaugmented lakes. The diversity indexes were directly correlated with inorganic carbon levels of the groundwater. As much as 549 kg of inorganic C can be added as bicarbonate to a lake, assming 7 days pumping at 2.18 million liters per day and an inorganic C concentration of 36 mg per liter in the groundwater. WATER QUALITY MANAGEMENT IN BRITISH COLUMBIA,
Pollution Control Board (British Columbia).
C. J. G. Mackenzie.
Canadian Water Resources Journal, Vol 5, No 3, p 69-77, 1980. 5 Ref.

Descriptors: *Canada, Water management, *Water policy, *Water quality management, *British Columbia, Water resources development, Fraser River, Okanagan River, Water pollution effects, Environmental effects, Wildlife, Fish, Recreation, Hydroelectric plants, Dams.

Water use policy in British Columbia has not been precisely enunciated. Two federal agencies with opposing interests are in charge of the Fraser River. Enhancement of the salmon fishery is not compatible with the efforts to improve navigation and port facilities on the lower river (dredging and filling of wetlands). Water quality in the Fraser and Okanagan systems is still good, but both basins are candidates for destruction as population and economic growth continues. In the Okanagan 100 years of disregard for an integrated land and water use policy have produced visible deterioration--silt in beach areas and proliferation of algae and littoral plants in lakes. Heavy metals and other pollution have been occurring with increasing frequency in the Fraser Estuary. Future water resources management will likely be in response to short-term commercial needs, with little regard for long-term implications. Even when wildlife, fish, and recreation are considered in master plans, results are often ineffective and expensive. For example, salmon ladders at the large Colorado river dams allowed adult fish to move upstream but blocked young fish from returning to the sea. It is expected that all major wild rivers in British Columbia will be tame within a generation. (Cassar-FRC)

VOLATILIZATION OF KETONES FROM WATER,
Geological Survey, NSTL Station, MS. Gulf Coast Hydroscience Center.
R. E. Rathbun, and D. Y. Tai.
Water, Air, and Soil Pollution, Vol 17, No 3, p 281-293, 1982. 2 Fig, 6 Tab, 35 Ref.

Descriptors: *Organic compounds, *Volatility, *Mass transfer, *Ketones, Fate of pollutants, Oxygen absorption coefficient, Liquid-film coefficient, Gas-film coefficient, Kinetics, Thermodynamics, Mathematical equations, Air-water interfaces.

Mass transfer coefficients for volatilization from water were measured in a laboratory water bath simultaneously with the oxygen adsorption coefficient for several ketones: acetone, 2-butanone, 2-pentanone, 3-pentanone, 4-methyl-2-pentanone, 2-heptanone, and 2-octanone. The liquid-film and gas-film coefficients of the 2-film model were determined for the ketones from the mass transfer coefficients. The % resistance of the liquid-film ranged from 37.6% for acetone to 74.7% for 2-octanone at low mixing conditions and from 10.8% for acetone to 37.1% for 2-octanone at high mixing conditions. The liquid-film coefficients for the ketones varied with the 0.719 power of the molecular diffusion coefficient, consistent with values reported in the literature. However, the liquid-film coefficients were variably dependent on molecular weight (-0.263 power for acetone to -0.378 power for 2-octanone). This disagreed with the constant -0.500 power assumed in the literature. Gas-film coefficients were independent of molecular weight, in disagreement with the -0.500 power assumed in the literature. The reason for these discrepancies may be that the organic materials used in the present work are very soluble in water whereas previous work dealt with slightly soluble organics. (Cassar-FRC)

EFFECTS OF WATERHYACINTH ON THE PHYSICOCHEMISTRY OF A SOUTH GEORGIA POND,
Clemson Univ., SC. Dept. of Zoology.
S. P. Schreiner.
Journal of Aquatic Plant Management, Vol 18, p 9-12, 1980. 3 Fig, 2 Tab, 11 Ref.

Descriptors: *Herbicides, *Water hyacinth, *Water quality, Aquatic weeds, Weed control, Aquatic plants, Dissolved oxygen, Nutrients, Grassy Pond, *Georgia, Water pollution effects, Detritus, Biomass.

Water quality and water hyacinth biomass and floating detritus were determined in three areas of Grassy Pond, Georgia, 97 ha in area and 2 m deep, in the summer of 1977. The three sampling sites were: old untreated, undisturbed mat; the edge of an undisturbed mat; and in a herbicide-treated area following 6 weeks of macrophyte regrowth. Water hyacinth and floating detritus (in kg per sq m dry weight), respectively, for the three sites were: old mat, 0.99 and 1.14; mat edge, 0.83 and 0.11; and herbicide-treated mat, 0.39 and 0.03. Water below untreated plants had lower oxygen, pH, and Eh and increased C02. In herbicide-treated areas water quality was similar to that of open water except for temporary decreases in 0 and increases in C02 and nutrients produced by plant decomposition. (Cassar-FRC)

INHIBITION OF NITRIFICATION BY ARSENIC, CHROMIUM, AND FLUORIDE,
College of Petroleum and Mineral, Dhahran (Saudi Arabia).
S. A. Beg, R. H. Siddiqi, and S. Ilias.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 482-488, May, 1982. 7 Fig, 2 Tab, 29 Ref.

Descriptors: *Inhibition, *Nitrification, Kinetics, Water pollution effects, Toxicity, Ammonia, Oxidation, Arsenic, Fluorides, Chomium, Fewrtilizers, Industrial wastewater, Shock loads, Wastewater treatment.

The inhibitory effects of arsenic, chromium, and fluoride on the nitrification process were investigated in a packed bed fixed film biological reactor. The nitrification reaction (ammonia oxidation) was independent of residual substrate concentrations, a zero-order reaction, for the conditions of the experiment, 60 and 120 mg per liter initial concentrations of ammonia. Nitrification was inhibited by Cr, As, and F under shock load conditions. The inhibited reaction was also zero-order. The inhibitor coefficients (the concentration of inhibitor that would inhibit the reaction rate by 50%) were 50 mg per liter for Cr (most toxic), 292 mg per liter for As, and 1218 mg per liter for F. Fertilizer plant wastewater contains 0-10 mg per liter Cr, 0-20 mg per liter As, and 0-200 mg per liter F. Therefore, at the upper limits of these concentrations, the inhibitory effect would be 17%, 7%, and 14% for Cr, As, anf F, respectively. (Cassar-FRC)

THE PHOSPHORUS CYCLE IN GERMISTON LAKE. II. THE IN VITRO AND IN SITU ABSORPTION OF 32-P BY POTAMOGETON PECTINATUS L,

Rand Afrikaans Univ., Johannesburg (South Africa). Research Group for Freshwater biology.
J. F. Vermaak, J. H. Swanepoel, and H. J. Schoonbee.
Water S. A., Vol 8, No 1, p 52-57, January, 1982. 3 Tab, 50 Ref.

Descriptors: *Phosphorus, *Macrophytes, Absorption, Nutrients, Germinston Lake, Potamogeton pectinatus, Translocation, Lakes, Cycling nutrients.

The effect of the soluble reactive phosphorus concentration on the adborption of phosphorus by the different organs of Potaogeton pectinatus L. was investigated. The effect of a higher soluble reactive phosphorus concentration in the root compartment on the absorption, translocation, and release of phosphorus by this species was also studied. The roots of P. pectinatus absorbed P32 in situ. both the roots and foliage of this species absorbed P32 from their respective environments, and both the roots and the foliage released a small fraction of the absorbed P32 after translocation. On the basis of this study, it was decided to use the compartmentalized container method to study the uptake and release of P32 by P. pectinatus in Germinston Lake on a seasonal basis. The results of this experiment, which showed the existence of a seasonal variance in phosphorus uptake, translocation, and release, will be presented later. (Baker-FRC)

5D. Waste Treatment Processes

POLLUTION: CLEANING UP WITH THE WATER HYACINTH,
J. F. Schlais.
Environment, Vol 22, No 5, p 5, 43, June, 1980.

Descriptors: *Wastewater treatment, *Water hyacinth, Biological oxygen demand, Suspended solids, Nitrogen, Phosphorus, *Wastewater lagoons, *Biological wastewater treatment, Chemical recovery.

In 1976, the National Aeronautics and Space Administration's National Space Technology Laboratory in Mississippi began using water hyacinths to treat the wastewater in its sewage lagoon. This action was taken on the advice of the head of the Laboratory's Vascular Aquatic Plant Program, who had been investigating the possibility of using the plant in waste reuse and water recycling systems on manned space flights. In 3 months, the water hyacinths cut the 5-day biological oxygen demand by 95 percent to 5 milligrams per liter and the total suspended solids by 90 percent to 10 milligrams per liter. In addition, the water hyacinths reduced ammonia and organically bound nitrogen by 73 percent and phosphorus by 57 percent. Water hyacinths used to treat a second lagoon, which received wastewater from the Laboratory's large general, photographic, and pesticide laboratory complex, were found to readily absorb and concentrate in their roots such pollutants as lead, mercury, cadmium, and organic compounds suspected of being carcinogenic. Although these plants must be disposed of in a manner designed to prevent the heavy metals from leaching out, it may be possible to recover valuable metals after several years. The water hyacinth can survive temperate winters, and an enclosed greenhouse system is being developed to facilitate use of this wastewater treatment method where freezing temperatures would kill the plant. Harvested plants can be sold as cattle food supplements, for use in producing methane, or as a fertilizer for sandy soils. Although evapotranspiration rates are high, use of greenhouse covers with special drainage pipes can result in the recovery of as much as 40 percent of the daily wastewater as pure freshwater. (Carroll-FRC)

DISINFECTION EFFICIENCIES OF CHLORINE DIOXIDE IN A GRAVITY FLOW CONTRACTOR,
Strauss and Roberts, Porterville, CA.
K. E. Longley, B. E. Moore, and C. A. Sorber.
Journal of the Water Pollution Control Federation, vol 54, No 2, p 140-145, February, 1982. 7 Fig, 4 Tab, 11 Ref.

Descriptors: *Disinfection, *Chlorine dioxde, *Bacteria, Viruses, *Coliforms, Mixing, *Wastewater treatment, Chlorine, Chlorination, Gravity flow contractors.

Chlorine dioxide and chlorine were evaluated as disinfectants for reduction of wastewater fecal coliforms and coliphages in a gravity flow contractor. Both disinfectants produced biphasic inactivation curves with most of the inactivation occurring within the first 3 minutes. Fecal coliforms were reduced by log 1.7 and log 5.1 by initial chlorine dioxide doses of 1.0 and 10.,0 mg per liter, respectively, at 30 minutes contact time. Coliphage inactivations were log 1.4 and log 3.7 for chlorine dioxide doses of 1.0 and 10,0 mg per liter, respectively, at 30 minutes contact time. A dose of 5 mg per liter chlorine reduced fecal coliforms by log 5.1 and coliphages by log 1.7. Chlorine dioxide was superior to chlorine as a disinfectant when both concentrations were expressed in terms of chlorine. Chlorine dioxide also produced very low disinfectant residuals. (Cassar-FRC)

COMPUTER-BASED IMPLEMENTATION OF COMBINED SEWER CONTROL,
EMA, Inc., St. Paul, MN.
T. M. Brueck, D. F. Peterson, and J. A. Nye.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 198-205, February, 1982. 12 Fig, 2 Ref.

Descriptors: *Combined sewers, *Sewer systems, *Control systems, Computers, Automation, Storm water, *Lima, *Ohio, Gates, Overflow, Storage, *Wastewater management, Wastewater collection.

A computer-controlled combined sewer system, operating the Lima, Ohio, since the spring of 1980, has provided accurate and responsive automatic control of storage and overflows during storm events, operational ease and flexibility, and a reduction in sewer system maintenance. The original computerized system, serving an area of about 1500 ha, included eight regulator/overflow stations and an interceptor lift station. Analysis of the existing computer system by simulation and field testing resulted in a new computer control system. This allows control of sewer gates for storage equalization, measurement of river overflow, and control of river gates to protect against in-system flooding. A CRT tube displays information about the sewer system in either overview or detailed form. Three modes of control (Downstream Storage, Equal Storage, and Dewatering) are used to achieve the objectives: to minimize upstream in-system flooding, to maximize rainfall in-system storage, to equalize diurnal flow variations to the treatment plant, to minimize gate operations, and to measure overflow to the river. (Cassar-FRC)

RELIABILITY AND STABILITY OF TRICKLING FILTER PROCESSES,
S. Niju, E. D. Schroeder, and R. S. Haugh.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 129-134, February, 1982. 3 Fig, 6 Tab, 7 Ref.

Descriptors: *Trickling filters, *Design criteria, *Reliability, *Stability analysis, Activated sludge process, *Wastewater treatment, Model studies, Statistical analysis, Biological oxygen demand, Suspended solids.

Concentrations of BOD and suspended solids in effluents from 11 trickling filter plants were statistically analyzed. Lognormal distribution functions fit these data. Since reliability and stability models developed for the activated sludge process fit the trickling filter data well, these models may be used to design a trickling filter plant of chosen reliability or to assess the reliability and stability of an existing plant. Plants with a standard deviation of 10 g per cu m or less BOD or suspended solids generally have maximum daily concentrations of these parameters which are less then 70 g per cu m. (Cassar-FRC)

TREATMENT OF CYANIDE WASTE BY THE EXTENDED AERATION PROCESS,
Delaware Univ., Newark. Dept. of Civil Engineering.
A. F. Gaudy, Jr., E. T. Gaudy, Y. J. Feng, and G. Brueggemann.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 153-164, February, 1982. 11 Fig, 1 Tab, 31 Ref.

Descriptors: *Cyanide, *Industrial wastewater, *Extended aeration, Aeration, Chemical wastewater, *Wastewater treatment, Biological treatment, Aeration, Sludge, Toxicity, Sewage bacteria, Hydrolytic assist.

Cyanide at levels of 10, 15, and 20 mg per liter was efficiently metabolized in a laboratory extended aeration process using a periodic hydrolytic assist to the autodigestive process. The hydrolytic assist controls the mixed liquor suspended solids level without wasting sludge. Steady feeding and prolonged acclimatization were necessary to achieve good efficiency and nitrification. Under these conditions cyanide was not detached in sludge or effluent. Sudden 5 mg per liter increases in cyanide concentrations produced severe upsets which required 2 to 4 weeks for recovery. The predominant organisms, Bacillus and Klebsiella, did not metabolize cyanide but survived up to concentrations of 90 mg per liter. Other cyanide-degrading organisms were present in the biomass. Experiments indicated that up to 60% of cyanide in the system was removed by stripping. This study showed that low concentrations of cyanide may be sewered to a public treatment works using the hydrolytically assisted extended aeration process without adverse effects. (Cassar-FRC)

ADVANCED WASTEWATER TREATMENT FOR GROUNDWATER RECHARGE--BERLIN RECHARGE PROJECT (RECYCLAGE ET TRAITEMENT D'EAUX USEES POUR RECHARGER UNE NAPPE SOUTERRAINE: L'INSTALLATION PILOTE DE BERLIN),
F. Sarfert.
Aqua, No 1, p 17-18, 1981. (No English summary).

Descriptors: *Wastewater treatment, *Advanced wastewater treatment, *Groundwater recharge, *Berlin, Germany, Filtration, Biological wastewater treatment, Infiltration, Aeration, *Groundwater management.

Infiltration fields have long been used for groundwater rechange in Berlin. Research is currently underway on optimal methods of treating wastewater prior to artificial recharge in order to produce groundwater of quality equaling that of natural groundwater. Following biological treatment, the wastewater passes through a flocculation tube, a settling basin, a dual media filter, and a pressure aeration tube. The water is infiltrated into the soil via two shafts 200 m deep. The infiltration field comprises a slightly sloping 10 m sand layer over an impermeable marl layer. Water sampling tubes are provided 100 m from the infiltration point. Significant reductions were achieved by the subterranean migration in suspended solids, BOD, DOC, COD, UV extinction, phosphate and E. coli titer. An ozonization stage is under construction. MICROBIAL DEGRADATION OF 14C-DIPHENYLAMINE IN A LABORATORY MODEL SEWAGE SLUDGE SYSTEM,
Food and Drug Administration, Wasnington, DC. Div. of Chemical Technology.
A. M. Gardner, H. G. Alvarez, and Y. Ku.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 1, p 91-96, January, 1982. 1 Fig, 1 Tab, 12 Ref.

Descriptors: *Activated sludge process, *Aromatic compounds, *Biodegradation, Organic compounds, Amines, Sludge, Model studies, *Wastewater treatment, Industrial effluents, Toxicity.

This report describes the biodegradation of diphenylamine in a laboratory model sewage sludge system. DPA is an aromatic amine, used as a stabilizer in propellants and as an antioxidant in polymers and rubber. The results of degradation experiments using three different 1.5 liter batches of sludge were virtually identical. The average recovery of added radioactivity was 82%. Sludge microorganisms produced some DPA metabolites which were more acutely toxic than the parent material. The metabolites identified suggest that DPA undergoes progressive oxidative metabolism in the sewage treatment process. DPA is probably first oxidized to 4-hydroxy-DPA and an isomeric compound. The oxidized ring is then cleaved, forming water soluble acids which are degraded further to aniline and carbon dioxide. After 6 hr incubation under the experimental conditions, the microbial degradation of DPA was incomplete, with more than 35% of the compound undegraded. Although the identified metabolites are more toxic than DPA, they are not persistent in the sludge mixed liquor after they are formed. (Baker-FRC)

BIODEGRADATION OF 14C-TRIS(2,3-DIBROMOPROPYL) PHOSPHATE IN A LABORATORY ACTIVATED SLUDGE SYSTEM,
Food and Drug Administration, Washington, DC. Div. of Chemical Technology.
G. H. Alvarez, S. W. Page, and Y. Ku.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 1, p 85-90, January, 1982. 1 Fig, 2 Tab, 13 Ref.

Descriptors: *Phosphates, *Activated sludge process, Environmental effects, Biodegradation, *Toxicity, Organic compounds, TRIS, *Industrial wastewater, Path of pollutants, Radioactivity effects.

The fate of tris(2,3-dibromopropyl) phosphate (Tris) in a laboratory activated sludge system was investigated. The distribution of radioactivity from various fractions of biodegradation studies was determined. The total recovery of the added radioactivity was 91%. Thin layer chromatography of petroleum ether extracts showed a single radioactive spot with the same Rf value as authentic Tris. The recovery of undergraded Tris was 55% after 24 hr. The mineralization of Tris by the sludge system was indicated by the C-14 labeled carbon dioxide in the trap, 6% of the added radioactivity. The half-life of Tris was estimated at 19.7 hr by least squares regression analysis. Ethyl ether extracts of both the solids and the aqueous phase contained 21% of the added radioactivity, and the majority of this radioactivity was present in the aqueous phase (18%). TLC of this fraction identified a single spot with Rf 0.64, identical to that of bis(2,3-dibromopropyl) phosphate. The radioactive compound in this fraction was isolated by TLC, methylated, and analyzed by GC/MS, and had a mass spectrum identical to the methyl ester of bis(2,3-dibromopropyl) phosphate. It was concluded that about 50% of the Tris was degraded in 24 hr, with the major metabolite being bis(2,3-dibromopropyl) phosphate. The toxicity and environmental consequences of this metabolite are not known. (Baker-FRC)

CONTROL OF ALUM ADDITION IN WASTEWATER TREATMENT,
Norsk Inst. for Vannforskning, Oslo.
T. Damhaug, J. F. Ferguson, H. Buset, and R. Brusletto.
Water Science and Technology, Vol 13, No 11-12, p 531-537, 1981. 7 Fig, 1 Tab, 13 Ref.

Descriptors: *Hydrogen ion concentration, *Phosphorus removal, Process control, *Chemical treatment, *Alum, *Wastewater treatment, Alkalinity, Phosphorus, Phosphate, Control systems, Carbon dioxide, Automation, Pilot plants.

Phosphate removal from wastewaters is achieved through the use of alum additions to control eutrophication of surface waters. Results of a national project on 'Instrumentation and Control of Chemical Treatment Plants' are discussed to consider various control strategies for process control which maintain the final pH within an optimum range. Full scale studies showed that in some cases a constant alum feed or time clocked program or flow proportional dosage is sufficient to provide an effective level of control. Numerous deficiencies in design and use were uncovered in a survey of plants using pH feedback control. The main dynamic problem was found to be the rapid deterioration of pH electrode time response. A method which avoids most of the problems of oscillations between the sensor and the chemical dosage with the resulting oscillations in effluent quality is an alkalinity feedforward process. An alkalinity measuring device based on the measurement of CO2 gas by a gas sensing electrode after the conversion of bicarbonate to CO2 was successfully tested in pilot plant studies. (Geiger-FRC)

STRATEGIES FOR THE CONTROL OF ACTIVATED SLUDGE PLANTS TREATING INDUSTRIAL WASTEWATERS,
Aware, Inc., Nashville, TN.
M. L. Duke, W. W. Eckenfelder, and M. E. Templeton.
Water Science and Technology, Vol 13, No 11-12, p 553-559, 1981. 5 Fig.

Descriptors: *Activated sludge, *Performance evaluation, *Biological oxygen demand, *Mathematical models, Process control, Sludge conditioning, Wastewater treatment, Industrial wastewater, Water quality standards, Oxygen uptake, Mathematical studies, Graphical methods, *Activated sludge process.

Mathematical models are presented which provide a rapid assessment of activated sludge plant performance and a guide for operational strategies. Oxygen uptake has been shown to be a useful parameter in the control of the activated sludge process. The effluent quality of a steady-state system may be viewed as a function of sludge age and the degradation properties of the wastewater. The specific oxygen uptake rate (SOUR) is also associated with sludge age and is therefore related to the effluent quality for any wastewater with defined degradation characteristics. For a given activated sludge plant, kinetic coefficients may be calculated from plant operating records and supplemental laboratory investigations. By plugging the coefficients into the mathematical model, graphical relationships of sludge, SOUR, and effluent quality may be obtained. (Geiger-FRC)

NEW FLOCCULATION UNITS WITH HIGH EFFICIENCY,
Bundesgesundheitsamt, Berlin (Germany, F. R.). Inst. fuer Wasser, Boden, und Lufthygiene.
A. Grohmann, M. Reiter, and U. Wiesmann.
Water Science and Technology, Vol 13, No 11-12, p 567-573, 1981. 9 Fig, 5 Ref.

Descriptors: *Flocculation, *Precipitation, *Colloids, *Phosphorous removal, *Design criteria, *Wastewater treatment, Phosphate, Turbidity, Municipal wastes, Separation techniques, Sedimentation, Coagulation, Mixing.

To design flocculation reactors with a more suitable flow pattern, the precipitation and flocculation of phosphate and turbidity caused by the model colloid, skim milk and from effluents of a municipal wastewater treatment plant were investigated. Preliminary studies demonstrated the profitability of performing mixing, precipitation and/or coagulation as well as flocculation in three different units. Flocculation was examined in two new reactors, a cylinder stirrer and a tubular reactor within a turbulent flow region. The mean residence time, concentration of chemicals, input of energy and the dimensions of the reactors were varied. In only 30 seconds, the turbidity and total concentration of phosphate could be reduced to 5% of their original levels. A lower specific energy input was required by the present system than with conventional flocculation units. (Geiger-FRC)

ADVANCED SUPERVISORY CONTROL SYSTEM FOR SLUDGE TREATMENT,
Meidensha Electric Mfg., Co., Tokyo, (Japan).
T. Imamura.
Water Science and Technology, Vol 13, No 11-12, p 575-580, 1981. 3 Fig, 3 Tab.

Descriptors: *Process control, *Digital computers, *Control systems, *Sludge digestion, Wastewater treatment, Automation, Sludge drying, Dewatering, Computers, Data transmission, *Sludge treatment.

A hard-wired logic for a micro-computer-applied distributed control system was designed to control sludge treatment (raw sludge system plus digestion sludge system) in a large-scale wastewater treatment facility. The system is composed mainly of graphic panels, an operation console, industrial instruments, auxiliary relays and other equipment for the supervision of process conditions, the operation of various devices, and automatic controls. The system may be expanded in accordance with the size of the treatment facility, with accompanying problems such as the expansion of installation space and an increase in required man-hours for operators. In the case of expansion or modification of the facility, the system proved less flexible, so that extreme modification or the complete replacement of the supervisory control system was required. (Geiger-FRC)

ULTRASONIC SENSORS FOR MONITORING FLOWS AND SLUDGE SOLIDS CONCENTRATIONS IN WATER AND WASTE-WATER TREATMENT,
Southampton Univ. (England).
W. Balachandran, and R. Briggs.
Water Science and Technology, Vol 13, No 11-12, p 581-588, 1981. 5 Fig, 7 Ref.

Descriptors: *Process control, *Automation, *Sensors, *Suspended solids, *Flow velocity, *Wastewater treatment, Sludge thickening, Dewatering, Sludge drying, Cost analysis, Monitoring, Control systems, Water treatment.

The monitoring of sludge solids concentration, mass and volumetric flows, and other parameters of sludge dewatering is important to water, wastewater, and sludge treatment processes. A technique based on the measurement of auto- and cross-correlation of turbulence-induced electrical noise using ultrasonic sensing equipment has been designed to optimize the monitoring process. Using two pairs of identical sensors, the suspended solids concentration and flow velocities of slurries and sludges have been successfully monitored. Since the system requires an engineered pipe section and various sensor housings for pipes of different diameters, it is a fairly expensive technology. If a reasonable market is established for this technology, significant price reductions should result. (Geiger-FRC)

APPLICATION OF ELECTRO-OSMOSIS TO DEWATERING SLUDGES,
Wroclaw Technical Univ. (Poland). Inst. of Environmental Protection Engineering.
E. S. Kempa, and J. Dobosz.
Water Science and Technology, Vol 13, No 11-12, p 589-592, 1981. 3 Fig.

Descriptors: *Dewatering, *Automation, *Industrial wastes, Sludge thickening, Process control,

Separation techniques, Control systems, Wastewater treatment, Electrochemistry, Sludge conditioning, *Sludge drying, *Electro-osmosis.

An electroosmosis technique was modified to allow automation of sludge dewatering sludge characterized by high specific resistance. The electroosmosis installation was altered by covering the anode with a thin layer of sludge to press it down and ensure humidity near the anode. A vertical flow of liquid ensures process continuity. The optimal potential gradient was 1 V/cm, and the water content of a sludge cake from a crystal-glass works using the technique was 45-50%. Other sludge systems achieved water contents of 60-70% of the total mass. Electroosmosis provided a removal of 80% of the heavy metals via the liquor with a total energy consumption of 80-200 kWh/cu m of sludge. The process has also been successfully applied to sludges from the industrial wastewaters of manufacturers of paints, varnishes, lacquers and synthetic fibers. (Geiger-FRC)

A DYNAMIC MODEL IDENTIFICATION OF THE SLUDGE DEWATERING PROCESS,
Kinki Univ. Osaka (Japan). Dept. of Electrical Engineering.
E. Bamba, S. Yamawaki, M. Yamamura, H. Kitagishi, and T. Yamashita.
Water Science and Technology, Vol 13, No 11-12, p 593-598, 1981. 2 Fig, 3 Tab.

Descriptors: *Mathematical models, *Dewatering, *Mathematical equations, *Process control, Wastewater treatment, Sludge, Mathematical studies, Sludge thickening, Model studies, Control systems.

An identification algorithm called the Revised GMDH (Group Method for Data Handling) algorithm is proposed which gives static and/or dynamic mathematical models. The dynamic mathematical models are used to prepare generalized control equations which are employed as part of a feedforward control that is sensitive to disturbances in the sludge dewatering process. The linearized control equations obtained allow complete control of the dewatering process. The results of this research will be used to design an optimal control system for the dewatering process by taking the appropriate performance index into account. (Geiger-FRC)

MANAGEMENT SYSTEM FOR CONTROL OF PROCESS LOSSES AND SPILLS IN THE KRAFT PULPING INDUSTRY,
Tufts Univ., Medford, MA.
G. W. Gove, and J. J. McKeown.
Water Science and Technology, Vol 13, No 11-12, p 545-551, 1981. 3 Tab, 3 Ref.

Descriptors: *Wastewater treatment, *Water pollution prevention, *Pulp wastes, *Digital computers, *Simulation analysis, Water pollution control, Industrial wastes, Computer models, Model studies, Analog computers, Mathematical studies, Mathematical models, Kraft mills.

A four-year project was carried out to evaluate analog and direct digital control systems designed to intercept and recover intermittent losses discharged from a kraft pulp mill. A design approach for evaluating spill tank capacity and routing systems through dynamic simulation modeling (DYNAMO) is also presented. Results showed that conductivity and flow could be successfully utilized as inputs to the control system along with values for pumping rate and tank level. Over a two-year trial period, sensors were maintained to yield a 90% reliability, while computer availability was nearly 100%. The intercepted material was returned to recovery rather than to the wastewater treatment facility. The spill control tank was generally kept at less than 20% full. (Geiger-FRC)

AN EXERCISE IN SLUDGE CONSOLIDATION,
W. Campbell, and D. D. McCallum.
Water Services, Vol 85, No 1029, p 551-552, 555, 1981. 2 Tab, 2 Ref.

Descriptors: *Design criteria, *Sludge thickening, *Wastewater facilities, *Separation techniques, Wastewater treatment, Costs, Sludge disposal, Sludge conditioning, Industrial wastes, Cost analysis, Activated sludge, Flocculation, Sludge filters.

The objectives, site investigation and design work carried out prior to the installation of a sludge consolidation plant at the Dextran pharmaceutical manufacturing plant in Holmes Chapel are presented. Sludge generated at the site is derived largely from a Flocor E biofilter system. Main considerations in the design of the sludge handling plant were cost savings (through reduced sludge transport costs), simplicity of operation, ability to handle future increases in sludge production, energy efficiency, odor-free operation, and minimal space requirements. Dewplant (ET) Ltd. was selected to conduct a laboratory investigation of process options and design and to cost out a suitable consolidation scheme based on their results. Laboratory studies showed that gravity separation without expensive flocculants would allow consolidation of raw sludge to 30-50% of its original volume. Duplicate mild steel tanks were used to perform the consolidation on the fill and draw principle. A new thickened sludge holding tank was supplied that provided advantageous disposal rates while meeting space requirements. Duplicate pumps could transfer both consolidated sludge and decanted liquors. Operating results proved satisfactory and have validated design figures. The reduction in volume of transported sludge in 1980 amounted to 575 cu m/month. The final cost savings of the method will depend on the available method of ultimate disposal. (Geiger-FRC)

PACKAGE ANAEROBIC SLUDGE DIGESTION.
Water Services, Vol 85, No 1029, p 556, 559, November, 1981.

Descriptors: *Anaerobic digestion, *Automation, *Wastewater treatment, *Sludge digestion, *Automation, *Farm wastes, Wastewater facilities, Solid wastes, Process control, Mixing, Sludge conditioning, Sludge utilization.

Anaerobic sludge digestion (ASD) reduces pathogens and odors while offering recovery of energy through methane production. ASD is usually feasible only for large wastewater treatment facilities. The retention time for ASD can be reduced to 15 days or less with careful attention to the loading design and heating and mixing systems. The use of steel digesters has cut capital costs and considerably reduced the construction requirements. The Farm Gas ASD plant features automated loading, mixing and heating systems that may be used as unmanned treatment works. Loading is performed by duty and standby positive displacement pumps. Raw sludge is loaded into the top of the digester through an overflow port and is then rapidly dispersed by an unconfined gas mixing system. The sludge is maintained at 35 degrees by means of heated water circulated through an array of tube heat exchangers. The water is heated from a boiler which burns digester gas, and backup heating is provided by electric immersion heaters. The excess gas is used for heating the facility or for payback power generation. An agreement was made in January of 1981 in which Degremont Laing, a subsidiary of Degremont SA of Paris, was licensed to exclusively market the Farm Gas range of ASD systems in the United Kingdom and Ireland. Contracts have already been awarded by Severn Trent Water Authority and the Department of the Environment for Northern Ireland for package ASD plants. (Geiger-FRC)

ISOLATION AND CHARACTERIZATION OF CELLULOLYTIC BACTERIA FROM ACTIVATED SLUDGE,
Louvain Univ. (Belgium). Lab. of Industrial Microbiology and Biochemistry.
K. Ramasamy, M. Meyers, J. Bevers, and H. Verachtert.
Journal of Applied Bacteriology, Vol 51, No 3 p 475-481, December, 1981. 4 Tab, 27 Ref.

Descriptors: *Activated sludge process, *Bacteria, Sewage bacteria, *Culture media, Cellulolytic bacteria, Aerobic bacteria, Cellulomonas, Pseudomonas, Wastewater treatment, Microbiological studies.

An attempt was made to characterize five strains of cellulolytic bacteria isolated from activated sludge using the solid media of Berg et al. and Pochon and Tardieu overlayered with Whatman No. 1 filter paper circles. Colonies appearing in 3-4 days of incubation in the dark at 28 C were transferred to slants of mineral salts medium overlayered with rectangular pieces of filter paper. Inocula from the slants were transferred to tubes of Dubos mineral solution containing a strip of filter paper. After disintegration of the filter paper occurred (3 days), the contents of the test tubes were homogenized, and dilutions were plated onto solid media containing cellulose powder, starch or silica gel overlayered with filter paper. Colonies which appeared pure were transferred to slants of mineral agar covered with filter paper strips. Isolates derived from filter paper overlayered media were mostly cellulolytic and tended to spread, so that incubation time was critical. Incorporation of other substances into the media decreased the percentage of cellulolytic colonies. The five strains studied in detail were rods with a single polar flagellum; strain DK showed a helical structure of the flagellum. The strains were Gram negative (or variable) and non-sporulating; they formed pigments of different colors on starch agar. Strain DK was probably a Cellulomonas and the other strains alcaligenes-like Pseudomonas, though they did not correspond completely to descriptions of known strains. (Carroll-FRC)

TREATMENT OF SECONDARY SEWAGE EFFLUENT WITH A PEAT-SAND FILTER BED,
Forestry Sciences Lab., Grand Rapids, MN.
D. S. Nichols, and D. H. Boelter.
Journal of Environmental Quality, Vol 11, No 1, p 86-92, January-March, 1982. 2 Fig, 6 Tab, 33 Ref.

Descriptors: *Filtration, *Wastewater treatment, *Phosphorus removal, Coliforms, Feces, Nitrogen, Phosphorus, Water quality, Plants, Tertiary wastewater treatment, Advanced wastewater treatment, Peat soils, Separation techniques, Microbial degradation, *Wastewater treatment.

To provide additional treatment of the secondary sewage effluent from a campground on the shore of North Star Lake a peat-sand filter bed was constructed. The lake is within the Chippewa National Forest in north-central Minnesota. The effluent contained an average of 30.9 mg/liter total nitrogen, 8.63 mg/liter total phosphorus, and 122,000 fecal coliforms/100 ml. From late May through early October an average of 6.8 cm/week was applied for an 8 year period. Almost complete removal of fecal coliform bacteria and phosphorus was achieved by the peat-sand filter bed. During the 2nd and 3rd years of operation about 90% of the wastewater nitrogen was removed. By the 5th year this level had declined to about 50% due to the oxidation of the peat and the release of nitrogen. The high iron, aluminum, and ash content of the peat contributed to the highly efficient removal of phosphorus by the filter. During the first 2 or 3 years of wastewater appplication the microbial immobilization in the peat contributed to nitrogen and phosphorus removal. In overall nitrogen and phosphorus removal, rough stalked bluegrass increased each year and accounted for 45% of the phosphorus and virtually all of the nitrogen removal from the wastewater in the fifth year of the study. PURIFICATION OF DYE WORKS EFFLUENTS WITH ACTIVE CARBON (REINIGUNG VON FARBEREIABWASSERN MIT AKTIVKOHLE),
Laboratorium fuer Adsorptionstechnik, G.m.b.H., Frankfurt am Main (Germany, F.R.).
J. Wirth.
Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 173-175, 1981. 5 Fig. English summary.

Descriptors: *Wastewater treatment, *Industrial wastewater, *Activated carbon, Adsorbents, Water reuse, *Dye industry wastes, Costs, Regeneration, Pilot plants.

Previous attempts to improve the quality of dyeworks effluents by treatment with ozone or flocculants have proven inadequate or expensive. In-plant reuse of treated water, desirable for cost savings and environmental protection, imposes high demands on treatment quality, resulting in residual dye levels below 0.1-0.2 mg/liter. To test the applicability of active carbon on a variety of dyes, adsorption isotherms were prepared, and filtration studies were performed on a laboratory apparatus. The column was able to be operated for 370 hr without dye breakthrough, regardless of the dye type and concentration tested. A small pilot filtration plant using a commercial active carbon was then installed in a dye works. A flow-through photometer was used for continuous measurement of the extinction after treatment. The purified water was almost completely colorless; however, inorganic salts were not removed by the column, nor was the slight turbidity due to textile auxiliaries. About 2 cu m of wastewater could be treated with 1 kg active carbon operated up to full loading. The active carbon was thermally reactivated and reused, allowing for reactivation losses of 5-10%. Only slight differences in coloration were apparent between lots of fabric treated with fresh water and reused water. Treatment costs were estimated at about 2.50 German Marks per cu m, approximately equal to the cost of fresh water. Additional savings would be realized by elimination of discharge fees. Therefore this process seems worthy of further investigation. (Carroll-FRC)

SELECTING ENERGY-EFFICIENT WASTEWATER TREATMENT SYSTEMS,
Resources Conservation Co., Seattle, WA.
T. M. Fosberg, D. Mukhopadhyay, T. M. O'Neail, and R. C. Whalen.
Chemical Engineering Progress, Vol 77, No 10, p 63-67, October, 1981. 5 Fig, 3 Tab.

Descriptors: *Industrial wastewater, *Energy, *Reverse osmosis, *Vapor compression distillation, Zero discharge, *Wastewater treatment, Distillation, Evaporation, Ponds, Waste disposal, Economic aspects, Brine disposal.

Reverse osmosis and vapor compression evaporation are energy-efficient methods of treating wastewaters from industries such as electric power generation, coal gasification/liquefaction, oil shale processing, and metal ore processing. These systems can be combined with evaporation ponds or mechanical drying equipment to achieve zero liquid discharge. The energy requirements (in kWh per 1000 gal wastewater) for these systems are as follows: reverse osmosis, 10; vapor compression evaporation brine concentration, 87; and combined reverse osmosis and vapor compression evaporation, 27. The preferred system for each application must also consider life cycle cost (vapor compression evaporation brine concentration is generally cheaper at lower energy costs of 3-5 cents per kWh) and the choice of pond evaporation vs. mechanical dryers (ponds are preferred for the Southwest and some parts of the West, whereas mechanical dryers are more suitable for the remainder of the country). SHALE OIL WASTEWATER TREATMENT BY EVAPORATION,
Battelle Pacific Northwest Labs., Richland, WA.
W. Wakamiya.
Chemical Engineering Progress, Vol 77, No 5, p 54-60, May, 1981. 10 Fig, 3 Tab, 7 Ref.

Descriptors: *Oil shale, *Industrial wastewater, *Evaporation, *Wastewater treatment, *Oil industry, Ammonia, Organic carbon, Sludge disposal, Petroleum industry.

Oil shale retort water, high in organic carbon and ammonia, was effectively treated by evaporation. A 95 liter per day laboratory evaporator removed over 90% of inorganic carbon, conductivity, alkalinity, total solids, and suspended solids. Removal of organic carbon was 70% and of ammonia, 86%. The quality of water produced from the process was high enough for use as irrigation water or boiler feed water. This distillate may also be injected into an aquifer, although the ammonia levels are 9 times higher than in groundwater. The sump concentrate is not suitable for incineration and may be classified as hazardous waste if arsenic and selenium levels exceed regulatory limits. Costs for the evaporation process, including ammonia stripping pretreatment, were estimated at $1.79 to $2.25 per cu m compared with $2.84-$6.51 per cu m for biological and physical treatment methods. (Cassar-FRC)

DESIGNING WASTEWATER TREATMENT SYSTEMS TO SAVE ENERGY,
Edeco, Inc., Tulsa, OK.
B. V. Prather, and W. J. Gossom.
Chemical Engineering Progress, Vol 77, No 10, p 68-77, October, 1981. 12 Fig, 4 Ref.

Descriptors: *Industrial wastewater, *Oil refineries, *Energy, Wastewater treatment, Design criteria, Filtration, Flotation, Gravity flow, Pumping, Operating costs, Oil wastes, Activated sludge process, Separation techniques, Mixing, Aeration, *Sludge disposal, Sludge thickening, Dissolved air flotation.

A procedure for designing petroleum refinery wastewater treatment systems applies rigorous sensitivity analysis to each component of the system to derive the most cost-effective system. The real effects of energy costs and costs of operator attention are balanced against treatment efficiency. Some of the most cost-effective processes are described. Maximum use of gravity flow and minimum differences in elevation for pumping wastewater can reduce pumping energy costs. In the primary treatment step oil/water gravity separators are desirable. Energy saving modifications of the process include part-time operation of skimmers and bottom rakes, proper choice of separator volume, and minimum mixing in equalization basins. Baffles may provide sufficient non-energy-consuming mixing in equalization vessels. In the intermediate step the dissolved air flotation process, which consumes more energy than sedimentation, may be more energy-efficient because it removes more pollutants. Suggestions for optimum design in the dissolved air flotation process include the eductor/emulsifier for producing fine air bubbles and optimum recycle pump design and operation. Secondary treatment by the activated sludge process may be optimized by a high sludge age, vertical upflow tanks, and good mixing. Other treatments for which energy requirements may be determined before choosing a final design are aeration/mixing, clarifiers, and sludge recycle pumps. Advanced treatment options include filters (gravity types are the most energy-efficient) and activated carbon. Land farming requires less energy than other sludge disposal methods. However, a sludge with sufficient oil content (16-18%) may be incinerated without additional fuel. (Cassar-FRC)

ANAEROBIC TREATMENT OF HIGH-STRENGTH WASTES,
Illinois Inst. of Tech., Chicago. Pritzker Dept. of Environmental Engineering.
A. W. Obayaski, H. D. Stensel, and E. Kominek.
Chemical Engineering Progress, Vol 77, No 4, p 68-73, April, 1981. 2 Fig, 5 Tab, 19 Ref.

Descriptors: *Anaerobic digestion, *Industrial wastewater, *Wastewater treatment, Aerobic treatment, Methane, Fluidized bed process, Biological treatment, Sludge blanket process, Design criteria, Retention time, *Cost analysis, Nutrient requirements.

Anaerobic system for treatment of high strength industrial wastewaters from food processing, pharmaceutical manufacturing, and distilleries can have annual costs 50% less for pretreatment and 18% less for complete treatment. Many improvements in the anaerobic process have been made within the last 15 years. In the contact process adequate solids retention time is maintained in spite of a reduction in hydraulic retention time. The upflow anaerobic sludge blanket process is the most significant advance in treatment of high-strength wastewaters. A full-scale system has been built to handle sugar beet waste. Other recent developments are the fluidized bed upflow reactor and the Clarigester, a clarifier over a digestion tank. Design of full-scale anaerobic system should begin with an evaluation of wastewater temperature, pH, potential toxic substances, the need for equalization, and nutrient requirements. Advantages of the anaerobic process are low sludge production, low nutrient requirements, no aeration required, 90% conversion of biodegradable organic matter to methane, seasonal operation possible, and high degree of waste stabilization at high loadings. Disadvantages are the lack of practical experience in full-scale operations, the long startup period, poor quality effluent, and sensitivity to variable loads and toxic substances. (Cassar-FRC)

TREATMENT OF COOLING TOWER BLOWDOWN,
Bechtel National, Inc., San Francisco, CA.
A. N. Rogers, M. C. Weekes, S. C. May, and E. H. Houle.
Chemical Engineering Progress, Vol 77, No 7, p 31-38, July, 1981. 3 Fig, 6 Tab, 9 Ref.

Descriptors: *Cooling towers, *Distillation, Reverse osmosis, *Wastewater treatment, Vapor compression distillation, Evaporation, Saline water, Vertical tube foaming evaporation, Scale, Heat transfer, Ponds, Energy, Costs, Operating costs, *Comparison studies.

Three treatments for cooling tower blowdown are compared: reverse osmosis, vapor compression, and vertical tube evaporation. No single process is definitely superior to the others in all aspects. Reverse osmosis requires the least plant investment. Vertical tube evaporation and reverse osmosis are lower than vapor compression in total annual costs. Reverse osmosis and vertical tube evaporation use about one-tenth the electricity that vapor compression does. Reverse osmosis has the largest ponding requirements, minimal long-term operating experience with blowdown, can be constructed in modular units, is very sensitive to upsets in pretreatment, and produces a fair quality product (salinity 475 ppm). Vertical tube foaming evaporation has moderate ponding requirements, no long-term operating experience with blowdown, is not practical to construct in modular units, is not too sensitive to upsets in pretreatment, and produces a high quality product (salinity 10 ppm). Vapor compression has moderate ponding requirements, a successful long-term history of operating with blowdown, is not practical to construct in modular units, is not too sensitive to upsets in pretreatment, and produces a high quality product (salinity 10 ppm). SPECIATION OF COPPER AND MANGANESE IN EFFLUENTS FROM THE ACTIVATED SLUDGE PROCESS,
Imperial Coll. of Science and Technology, London (England). Public Health Engineering Lab.
R. M. Sterritt, and J. N. Lester.
Environmental Pollution, Series A: Vol 27, No 1, p 37-44, January, 1982. 3 Fig, 1 Tab, 19 Ref.

Descriptors: *Activated sludge process, *Heavy metals, *Wastewater treatment, Copper Manganese, Effluents, Industrial wastes, Sludge.

The solubility and soluble speciation of heavy metals in effluent samples from an activated sludge simulation were investigated. An attempt was made to relate these phenomena to the capacity of the activated sludge process to remove them. A continuous flow laboratory scale activated sludge simulation system was employed. Ten heavy metals, silver, cadmium, cobalt, chromium, copper, manganese, molybdenum, nickel, lead, and zinc were added continuously to the aerator at nominal influent concentrations in the range of 0.01-0.50 mg/liter. The system was operated at sludge ages of 6, 9, 12, 15, and 18 days, maintained by wasting an appropriate quantity of mixed liquor. Samples of effluent were taken after the system had reached stability at each sludge age. Soluble metal was taken to be that which passed a 0.22 micrometer pore size. The proportions of total copper and manganese in solution were greater than 50% for sludge ages of 6-15 days, but fell to 18% and 7%, respectively at a sludge age of 18 days. This appeared to coincide with an increase in the effluent suspended solids concentration from 25 mg/liter to 50 mg/liter, possibly indicating that the solids had adsorbed significant quantities of both metals. No effect of chemical oxygen demand on metal solubility could be observed, as this parameter did not change appreciably with sludge age. Gel filtration indicated that both copper and manganese were maintained in solution by organic metal-binding fractions, although each metal was associated with different fractions. Copper speciation in the effluent changed with increasing sludge age, whereas forms of manganese were little changed. The data obtained indicate that the association of copper and manganese with different metal binding components may be related to differences in their observed removal efficiencies. (Baker-FRC)

ACCLIMATION OF SLUDGE FOR EFFICIENT REMOVAL OF NITROGEN FROM FERMENTATION WASTEWATER,
Kogyo Co. Lt., Bofu (Japan).
M. Nagashima, S. Noguchi, and T. Suzuki.
Journal of Fermentation Technology (Osaka), Vol 59, No 1, p 49-53, 1981. 5 Fig, 3 Tab, 5 Ref.

Descriptors: *Activated sludge process, *Denitrification, *Nitrogen removal, *Wastewater treatment, Nitrates, Nitrites, Nitrification, Nitrous oxide, Fermentation.

Activated sludge acclimated to nitrates and to nitrites differed in their ability to remove nitrogen from fermentation wastewaters. At a given BOD the nitrite sludge reduced nitrite at 2 or 3 times the rate at which nitrate sludge reduced nitrate. Nitrous oxide was formed with the nitrate sludge under high loads of nitrate and BOD but was minimized by rapid recycling and mixing. The nitrate sludge was converted to nitrite sludge by maintaining alkaline pH and high influent loads. (Cassar-FRC)

STUDIES ON BIOLOGICAL NUTRIENTS REMOVAL FROM FERMENTATION WASTEWATER (III). OPERATIONAL CONDITIONS ELIMIATING THE EVOLUTION OF NITROUS OXIDE IN A DENITRIFICATION PROCESS,
Kyowa Hakko Kogyo Co. Ltd., Bofu (Japan).
M. Nagashima, S. Noguchi, and T. Suzuki.
Journal of Fermentation Technology, Vol 59, No 1, p 55-58, 1981. 2 Fig, 3 Tab, 5 Ref.

Descriptors: *Activated sludge process, *Denitrification, *Nitrous oxide, Fermentation, *Wastewater treatment, Nitrates, Nitrites, Hydrogen ion concentration.

Nitrous oxide formation from two types of activated sludge was studied in laboratory batch operations. Sludge acclimated to nitrate readily reduced nitrate to nitrite. However, nitrite accumulated and nitrous oxide was evolved under these conditions, especially at acidic and alkaline pH. Sludge acclimated to nitrite reduced both nitrite and nitrate to gaseous nitrogen without evolution of nitrous oxide at any pH tested. The results help explain the previous finding that a rapid circulation of liquid between nitrification and denitrification basins eliminated the evolution of nitrous oxide, which is desirable in order to prevent secondary pollution. EFFECT OF ROTATION SPEED ON REACTION RATE ON A ROTATING BIOLOGICAL CONTACTOR,
Tokyo Inst. of Tech., Yokohama. Research Lab. of Resources Utilization.
S. Odai, K. Fujie, and H. Kubota.
Journal of Fermentation Technology, Vol 59, No 3, p 227-234, June, 1981. 9 Fig, 2 Tab, 5 Ref.

Descriptors: *Biological treatment, *Rotation speed, *Wastewater treatment, Glucose, Model studies, Rotating biological contactors.

The effect of the rotation speed of the discs of a rotating biological contactor on the biochemical reaction rate in the microbial film was simulated by a mathematical model. This effect was expressed as a rotation factor, which describes the relation between the time-average reaction rate and the rotation speed of the biodisc. The empirical equation, tested in a glucose oxidation experiment, produced results in agreement with the experimental results. The rotation factor is useful in predicting the power economy of the system, which depends on the disc rotation speed. (Cassar-FRC)

KINETIC CONSIDERATIONS ON THE PERFORMANCE OF ACTIVATED SLUDGE REACTORS AND ROTATING BIOLOGICAL CONTACTORS,
Rome Univ. (Italy). Ist. di Chimica Applicata ed Industriale.
A. E. Paolini, and G. Variali.
Water Research, Vol 16, No 2, p 155-160, February, 1982. 5 Fig, 4 Tab, 18 Ref.

Descriptors: *Activated sludge process, *Kinetics, *Wastewater treatment, Sludge, Activated sludge, Biological oxygen demand, Films, Thin films, *Industrial wastes, Hydraulics, Mathematical studies, Effluents, Performance evaluation, Comparison studies.

A study was designed to compare the performance characteristics of laboratory scale activated sludge and rotating biological contactor (RBC) plants treating the effluent from an urban solid waste processing industry, to verify a simplified design equation for RBC systems and evaluate the possibility of using the kinetic constants of suspended growths for fixed microbial films, and to develop an estimation procedure for the effective surface area of biofilms. A steady-state kinetic model for completely mixed activated sludge reactors with solids recycle and soluble substrate has been used in this study for correlating the experimental results and evaluating the kinetic constants of the suspended growth. Within the range of hydraulic detention time examined, 0.3 to 1.7 days, the activated sludge and RBC units showed very similar biological oxygen demand-5 removal kinetics when the activated sludge concenration and the geometric area of the discs per unit volume of aeration reactor are 2000 mg VSS/liter and 1340 square centimeters/liter, respectively. For disc rotational speeds not limiting microbial growth, a simplified kinetic equation as employed successfully to predict the steady-state performance of RBC systems under conditions of both varying organic loading and varying influent substrate concentration. Also, the kinetic constants of suspended microbial growth may be effectively included in this equation. This equation proves quite useful in evaluating the effective surface area of the biofilm. SURFACTANT ADSORPTION ON THE WOOL CARBONIZING WASTE (ADSORPTION DE SURFACTANTS SUR LE DECHET LAINIER DE CARBONISAGE),
Ecole Nationale Superieure de Chimie, Toulouse (France), Laboratoire de Chimie Organique et d'Agrochimie.
F. Perineau, J. Molinier, and A. Gaset.
Water Research, Vol 16, No 2, p 189-197, February, 1982. 7 Fig, 5 Tab, 21 Ref. English summary.

Descriptors: *Surfactants, *Wastewater treatment, *Absorption, Wool, Industrial wastes, Acidity, Temperature effects.

Wool carbonizing waste is composed mostly of chemically modified short sized wool fibers and of plant material particles considered as sulfuric lignins. Wool carbonizing waste was considered likely to be a suitable material for the absorption of ionic organic solutes from industrial waste water due to its physical structure as well as to the polar and apolar characteristics of its macromolecules. The absorption isotherms of anionic, cationic, and nonionic surfactants were drawn from various pH and temperature conditions to determine the absorption mechanisms involved as well as the absorption capacity of the carbonizing waste and the optimal absorption conditions. Temperature induced changes in absorption structure enhanced the absorption characteristics. Therefore wool carbonizing waste was proposed for the purification of hot effluents. The processing of anionic surfactant solutions requires acidic media, whereas alkaline media are more suitable for effluents containing cationic surfactants. In both cases ionic bonding is involved. The absorption isotherms have an L-shape, which corroborates the successive involvement of ionic and hydrophobic interactions in the case of ionic surfactants. Langmuir and Freundlich models were used for modeling of water processing units. The processing of industrial effluents in a stirred reactor corroborated the outstanding ability of wool carbonizing waste to absorb cationic surfactants. The tests also showed that the removal of non-ionic surfacta nts is improved when they are mixed with anionic surfactants. (Baker-FRC)

GEOCHEMICAL ANALYSIS OF THE STATE DRINKING WATER STANDARD GOST 2874-73 AND WAYS TO IMPROVE IT,
All-Union Scientific Research Inst. of Hydrogeology and Engineering Geology.
S. R. Krainov, I. Y. Sokolov, and M. S. Galitsyn.
Water Resources, Vol 8, No 2, p 164-173, March-April, 1981. 2 Fig, 2 Tab, 16 Ref. Translated from Vodnye Resursy, No 2, p 109-119, March-April, 1981.

Descriptors: *Water quality standards, *Drinking water, *Geochemistry, Standards, Groundwater, Water analysis, Mineral water, Public health, Chelation, Metals, Organic compounds, Chemical composition, *USSR.

Creation of optimal state (USSR) drinking water standards and methods of analysis is only possible with close cooperation between hygienists and specialists in geochemistry. As a result of natural processes, groundwater may contain elements in concentrations higher than the maximum allowable concentrations (MAC). Water containing toxic elements or organic compounds derived from wastewater are covered by the standards, but those

LIBRARY U. OF I., URBANA-CHAMPAIGN

with high mineral contents from natural processes are not. An additional problem is the standardization of certain elements in forms which do not exist in all waters. For example, molybdenum is standardized as Mo(2+) and Mo(6+), but in natural water molybdic anions are predominant. Similarly Se, standardized as SE(4+) and Se(6+), is found in groundwater as HSe03(-), Se03(2-), and HSe(-). The same situation occurs with Be, Pb, Cu, Zn, Fe, and Mn. Many standardized analytical methods do not detect the true concentrations of the elements in question, for example, complexed metals (Fe). The effects of elements vary according to the chemical form. Flourine is most hazardous in sodium bicarbonate waters and much less in BF(-) compounds. The authors state that the drinking water standards should not have MACs lower that the global background concentrations of these elements in natural groundwater. Background levels of Zn, Cu, Mg, Pb, and U are always less than the MAC except in acid or sulfide waters; background levels of Sr, F, Fe, Mn, As, Se, and Be are often near MAC levels. Natural waters high in one or morre of the elements under discussion are identified. (Cassar-FRC)

PROSPECTS OF USING RADIATION WATER TREATMENT METHODS,
P. I. Dolin, and S. A. Brusentseva.
Water Resources, Vol 8, No 2, p 201-205, March-April, 1981. 14 Ref. Translated from Vodnye Resursy, No 2, p 151-155, March-April, 1981.

Descriptors: *Radioactivity, *Disinfection, Reviews, *Wastewater treatment, Industrial wastewater, Detergents, Flotation, Oxidation, Polymers, Animal wastes, Activated carbon, Color removal, *Water treatment, Humic acids.

Radiation disinfection of wastewaters is presently the most promising method of using radiation in water treatment, according to a review of recent developments in this field. It is not clear whether microorganisms are killed by a direct hit of radiation energy or by radiolysis products of water (OH, N, or hydrated electrons). Accelerated electrons (energy 9 MeV, dose 0.2 Mrad) have been used with bubbling air to disinfect wastewater from livestock complexes, producing 100% disinfection of salmonellas, E. coli, and helminth embryos. Radiation plus the action of atmospheric oxygen produces decolorization, removal of tastes and odors, and disinfection of natural waters containing humic substances. Radiation-induced polymerization has been used to treat black liquor from the sulfite papermaking processing with 80-85% removal of lignin. It is also suitable for removing urea and certain dyes. The radiation flotation method in foam has been applied to treatment of wastewater containing nonbiodegradable synthetic detergents (alkyl aryl sulfonates) to reduce foam formation, increase surface tension, and decompose the detergent at the rate of 50 molecule per 100 eV. Organic pollutants extracted into a foam layer may be readily oxidized by this process. Co60 radiation treatment of activated carbon during livestock wastewater treatment prolongs the life of the carbon and produces a highly effluent. (Cassar-FRC)

TRY CHEMICAL TESTS IF INDUSTRIAL WASTES ARE STRONG,
K. A. Bradstreet.
American City and County, Vol 97, No 2, p 26-27, February, 1982. 2 Fig.

Descriptors: *Sewer infiltration, *Flow measurement, *Wastewater treatment, Industrial wastes, Rainfall, Lithium chloride, Wastewater facilities, Secondary wastewater treatment, *Derby, *Connecticut.

Engineers in Connecticut turned to a chemical dilution flow measurement method to determine how greatly infiltration and inflow were adding to a treatment plant's load. The sewage treatment plant in Derby was upgraded in 1973 to include secondary treatment. However, at times when the regulating chambers malfunctioned, excessive flows overloaded the treatment plant, interrupting plant operation. Traditional flow measuring techniques could not be used because large portions of the system were consistently surcharged during high groundwater and storm periods. Some sort of dilution procedure was needed, and lithium chloride was selected as the dilution agent. This compound is ideally suited for this use, as it is rare in most sewer systems, relatively nontoxic and easily measured using an atomic absorption spectrophotometer equipped with a lamp for lithium analysis. It is not affected by chemical reactions which may occur when it is fed into the sewer system. Once samples have been analyzed and flow rates determined, estimates of infiltration and inflow were made. Estimated inflow rates were adjusted based on the ratio of intensity of the rainfall during the gauging compared to expected rainfall intensity during a 10 year storm. (Baker-FRC)

LITERATURE STUDY OF THE BIODEGRADABILITY OF CHEMICALS IN WATER: VOLUMES 1 AND 2,
Franklin Research Center, Philadelphia, PA.
J. Geating.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-100843, Price codes: A11 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-175/176, October, 1981. 4 p, 1 Fig, 1 Tab, 1 Ref. R806699-01.

Descriptors: *Biodegradation, *Wastewater treatment, *Inhibition, *Mathematical models, *Molecular structure, Model studies, Chemical interference, Bibliographies, Microbial degradation, Microorganisms, *Chemical degradation.

This project was initiated to compile and review post-1974 literature references on aqueous biodegradability of chemicals, to update a previous report. Additionally, literature back to 1913 was searched for inhibitory effects of specific chemicals on wastewater treatment processes. Results are presented as an in-depth hierarchical index and bibliography of 600 items. The index is searchable at three levels: chemical name or chemical class; name of microorganism or type of microbial population affecting or being affected by the chemical; and wastewater treatment process. A structure-activity model was developed to distinguish between biodegradable and nonbiodegradable chemicals. Two parameters were used in the biodegradability model: molecular weight and Wiswesser Line Notation (WLN) based substructural keys. The WLN-based keys are based on major modification of the CROSSBOW program. In a test of the structure-activity model, 270 of 292 degradable compounds, or 92.5% were correctly classified whereas 39 of 57 (68.4%) nondegradable compounds were correctly classified. A total of 25 compounds could not be classified by the model. (Moore-SRC)

DATA BASE FOR INFLUENT HEAVY METALS IN PUBLICLY OWNED TREATMENT WORKS,
Tennessee Univ., Knoxville. Dept. of Civil Engineering.
R. A. Minear, R. O. Ball, and R. L. Church.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-108168, Price codes: A13 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-220, October, 1981. 5 p, 2 Fig, 1 Tab, 1 Ref. R805606-01.

Descriptors: *Heavy metals, *Wastewater composition, *Wastewater facilities, *Influent water, Industrial wastewater, Wastewater analysis, Seasonal variation, Waste load, *Wastewater treatment.

The heavy metals loading to publicly owned treatment works (POTW's) is of interest because of: the possible inhibitory effect it has on the biological treatment process; the effluent levels that can be achieved as a function of influent concentration; and the practice of land disposal of waste sludge. Data on influent heavy metals were obtained from 239 wastewater treatment plants. Wastewater treatment plant laboratories were evaluated during the study and generally found to be satisfactory within the framework of the evaluation method. Of the 80,000 individual items of data from the 239 plants, a substantial data base was generated for cadmium, chromium, copper, nickel, lead, and zinc. Extensive data were obtained for silver, arsenic, and mercury. Limited data were obtained for beryllium, cobalt, antimony, and selenium. Aluminum, iron, and manganese data were obtained as well. Overall, the individual plant mean and median metal concentration data tend to fit a log normal distribution. Though no association could be determined between the percent of industrial effluent and metal concentrations in POTW influents, sufficient data were available to determine that cities with less than 4% industrial contribution had significantly lower levels of cadmium, chromium, copper, mercury, nickel, and zinc. Only lead concentrations were not significantly different for the two populations. There were seasonal variations in metal concentration, from 5% to 20% greater in the fall than in the spring. HEAVY METAL SOURCES AND FLOWS IN A MUNICIPAL SEWAGE SYSTEM: LITERATURE SURVEY AND FIELD INVESTIGATION OF THE KOKOMO, INDIANA, SEWAGE SYSTEM,
Purdue Univ., Lafayetta. IN.
K. J. Yost, R. F. Wukasch, T. G. Adams, and B. Michalczyk.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-108366, Price codes: A13 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-224, October 1981. 3 p, 4 Tab. R805361-01.

Descriptors: *Heavy metals, *Cyanide, *Wastewater, *Sludge disposal, *Sampling, Copper, Chromium, Cadmium, Zinc, Nickel, Lead, Pollution load, *Wastewater treatment, Domestic wastes, Land disposal, Pollutant sources, Kokomo, Indiana.

The mass flows of heavy metals (Cu, Cr, Cd, Zn, Ni, Pb) and cyanide in the Kokomo, Indiana, collection system and wastewater treatment plant were analyzed. The primary objectives were to determine the relatve contributions of domestic and nondomestic sources to the total pollutant load in the system, and to assess the levels of discharge control required for the disposal of municipal sludge by landfill or agricultural land spreading. Sampling was conducted at point source locations, in major sewer trunklines and feeder lines, and at the treatment plant. Production and waste treatment data were presented for point sources sampled to characterize metal and cyanide discharges as a function of these parameters. A heavy metals mass balance was attempted for the treatment plant. Metal removal factors were presented for various plant operations. With the exception of lead, metals were found to be largely from nondomestic sources. With the exception of nickel, the Kokomo treatment plant removed 80% to 90% of the influent metals. Required reductions in nondomestic sources of metals to meet EPA landspreading guidelines for sludge were 98% for cadmium, 84% for zinc, and 42% for copper.. A simple statistical approach was presented for the design of a cost-effective sampling program for correlating point source and trunkline pollutant sampling. The purpose was to minimize the amount of sampling required to account for pollutants seen in trukline and treatment plant streams in terms of discharges from specific sources. (Author's abstract)

ENGINEERING AND ECONOMIC ASSESSMENT OF AUTOHEATED THERMOPHILIC AEROBIC DIGESTION WITH AIR AERATION,
Camp, Dresser, and McKee, Inc., Boston, MA.
P. W. Keohan, P. J. Connelly, and A. B. Prince.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102310, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency Project Sum-

mary EPA-600/S2-81-171, October 1981. 4 p, 2 Fig, 1 Tab.

Descriptors: *Aerobic digestion, *Sludge digestion, *Cost analysis, *Aeration, Economic aspects, Sludge drying, Disinfection, Pathogens, Biodegradation, Thermophilic bacteria, Heavy metals.

A major disadvantage of aerobic digestion is that its efficiency is greatly reduced during periods of cold weather. If heat losses are controlled, it becomes possible for the digester system to maintain its operating temperatures within the thermophilic range despite severe winter conditions. Engineering and economic analyses were made of test results obtained in experiments on a modified sludge stabilization process termed autoheated thermophilic digestion (ATAD) with air aeration. Test results were analyzed for system kinetics, heat balance, aerator transfer efficiency, pathogen destruction, dewaterability, and heavy metal interactions. Additionally, economic viability of ATAD was examined using very conservative criteria in application to facilities of 1, 10, and 100 mgd capacity. ATAD with air eration is found to be feasibile on a thickened municipal sludge. The favorable economics at plants of 1 mgd capacity merits serious consideration in planning for design of sludge processing facilities. In general, the characteristics of sludge processed by ATAD to a 40% reduction in volatile solids should be similar to those of sludge processed by ambient aerobic digestion or mesophilic anaerobic digestion. CARBOHYDRATES AND PROTEINS REMOVALS IN ACTIVATED-SLUDGE PROCEDURE,
Wroclaw Technical Univ. (Poland). Inst. of Environment Protection Engineering.
K. Barteszewski.
Acta Hydrochimica et Hydrobiologica, Vol 8, No 1, p 89-96, 1980. 7 Fig, 1 Tab, 8 Ref.

Descriptors: *Carbohydrates, *Proteins, *Activated sludge process, Biological treatment, Glucose, Albumin, *Wastewater treatment, Organic loading.

Six synthetic wastewaters, differing in protein concentrations (0 to 198 g albumin per cu m) and carbohydrate concentrations (10 to 647 g glucose per cu m) were subjected to laboratory-scale activated sludge digestion by biomass adapted to high-protein wastewaters. Suitable analytical methods were the pheno method for carbohydrates and the Lowry method for proteins. Removal of the carbohydrates and proteins proceeded in several stages. First, sorption occurred on the surface of flocs, slightly decreasing the concentration of organic matter. Second, protein levels increased temporarily, then gradually decreased. In wastewaters with high carbohydrate levels, carbohydrate concentrations decreased with simultaneous hydrolysis of proteins. When protein hydrolysis was complete, decomposition of both carbohydrate and proteins proceeded simultaneously. A wastewater containing high levels of carbohydrate and no protein degraded only after adaptation; decomposition was linear, not exponential, as in the mixed wastewater. Wastewater containing no protein at the beginning of degradation showed a slight rise in protein levels as the digestion proceeded due to the death of some of the microorganisms. (Cassar-FRC)

TREATING PHENOL RESIN PLANT WASTES,
S. R. Gelman, G. A. Mooney, and H. Craven.
Industrial Wastes, Vol 28, No 1, p 32-35, January-February, 1982. 4 Fig.

Descriptors: *Industrial wastes, *Wastewater treatment, *Phenols, Aerated lagoons, *Resins, Plastics, Biological wastewater treatment.

A two-phase program was instituted at a Georgia phenolic resin plant in efforts to rehabilitate the existing effluent ponds to meet discharge standards and to develop the long-range procedures and facilities needed in order for the plant to meet discharge standards year round under the existing and projected wastewater loadings. Wastewater treatment at the plant consists of two aerated lagoons which may be operated either in series or in parallel. The system provides pretreatment prior to discharge to a municipal sewer. A treatability study was conducted, and the data from that study were used in setting guidelines for treatment system operation. These guidelines have enabled operators to control waste flow into the treatment ponds in a manner that ensures discharge limit compliance. Mass limits were set for biochemical oxygen demand and chemical oxygen demand above which the system would fail. Raw waste is analyzed daily. Allowable flow is then computed from the limits. Prior to the study the operators would pump into the pond the amount of waste generated the previous day. They now pump the maximum volume that will maintain the prescribed phenol or chemical oxygen demand mass limit. Implementation of the results of this study along with increased operator monitoring and attention has considerably improved phenol removal performance and provided highly consistent treatment operations. BIOLOGICAL NITRIFICATION OF INDUSTRIAL WASTEWATER,
M. Olthof, and J. A. Oleszkiewicz.
Industrial Wastes, Vol 28, No 1, p 29-30, January-February, 1982. 5 Fig.

Descriptors: *Wastewater treatment, *Nitrification, *Activated sludge process, Industrial wastes, Biological wastewater treatment, Nitrogen, Nitrates, Ammonia, Chemical reactions.

Data are presented from two studies on ammonia removal from industrial wastes - one on coke oven effluents and one on a waste acid handling facility. The information was collected to define some of the factors affecting the ammonia removal in a one stage activated sludge system, with particular emphasis on optimization of the biological system with reference to sludge separation, removal rate and temperature effects, and without regard to denitrification facilities that would have to follow. The general trend appears to be a decrease in effluent ammonia concentration with decreased loading. Good sludge separation and control over the final solids carryover is essential to proper management of the bio-systems, since the active nitrifying organisms account for only 3 to 9% of the microorganism biomass of activated sludge, and are the lightest and thus most easily lost from the system. A decrease in chemical oxygen demand to nitrogen ratio was achieved by increasing the nitrogen concentration from 125 to 1,000 mg/l, which yielded substantial increases in the rate of removal in spite of ammonia concentrations in the reactor exceeding 250 mg/l at higher loadings. The temperature exerted a profound effect on all biological systems. The significant effect of temperature on nitrification accounts for the seasonal variation in effluent quality from the existing full scale plants. The successful operation of the biological ammonia nitrogen removal system is dependent on adequate supply of phosphorus and oxygen to oxidize ammonia to NO2 and NO3. (Baker-FRC)

RAILROAD'S SHOPS CORRECT AN OILY WASTES PROBLEM,
Nalco Chemical Co., Oak Brook, IL.
R. Cardile, and R. Fronczak.
Industrial Wastes, Vol 28, No 1, p 20-40, January-February, 1982. 1 Fig, 3 Tab.

Descriptors: *Wastewater treatment, *Sludge, *Industrial wastes, Oil, Oil wastes, Wastes, Railroad industry, Oil recovery, *Railroads, Sewers, *Milwaukee, *Railroad yards.

Design and construction changes were made by the Chicago, Milwaukee, St. Paul and Pacific Railroad in an effort to bring the existing treatment facilities at the Milwaukee Shops into compliance with their NPDES permit and local sewer ordinances. In the storm water treatment system, sludge generated from the IAF unit was originally designed to flow into the sludge holding tank and be dewatered on the belt press. The IAF units were designed to perated at a constant flow level through a range of influent flow conditions controlled by a pneumatically operated butterfly valve on the discharge line from the unit. However, this valve was unable to maintain the desired constant level condition. Due to the length and number of weirs in the IAF units, the level in the tank fluctuated so that either too little sludge was removed, resulting in lower quality effluent, or too much sludge was conveyed to the holding tank, causing it to overflow. After various changes had been made, the plant plant operated satisfactorily and allowed the Milwaukee Road shops and Yards to meet requirements. The belt press has proven to be an effective sludge dewatering technique for oily type sludges of railroad treatment facilities. The plant has recovered free oil as a valuable byproduct of the operation of the railroad's shops. Additional methods of sludge treatment are being considered by the firm to further increase oil recovery by releasing oil bound in sludge solids. (Baker-FRC)

SELECTIVE PASSAGE OF HYDROPHILIC NITROGENOUS ORGANIC MATERIALS THROUGH MACRORETICULAR RESINS,
Harvard Univ., Cambridge, MA. Div. of Applied Sciences.
N. M. Ram, and J. C. Morris.
Environmental Science and Technology, Vol 16, No 3, p 170-174, March, 1982. 3 Tab, 2 Fig, 26 Ref.

Descriptors: *Resins, *Filtration, *Organic compounds, Nitrogen, Humic acids, Water treatment, Adsorption, Carbonates.

Filtration of water samples through a combination of macroreticular resins XAD-8 and Tenax GC was examined as a method of selectively removing hydrophobic carbonaceous materials, such as humic acid, from aqueous solution. Such a method as this might be used as a pretreatment step in the analysis of N-organic hydrophilic substances by first selectively adsorbing potentially interfering hydrophobic materials from solution. The inability of N-organic substances to be absorbed onto the macroreticular resin combination was examined. Prefiltration of the natural water samples selectively removed hydrophobic carbonaceous organic materials without significantly affecting hydrophilic nitrogenous organic substances. Hydrophobic carbonaceous adsorbates competitively decreased adsorption of hydrophilic materials. This phenomenon permits high recoveries of organic nitrogen while simultaneously removing humic material. (Baker-FRC)

HOW SCREEN MOUNTING AFFECTS MICROSCREENING HYDRAULICS,
Envirex Inc., Waukesha, WI.
J. W. Wittmann.
Water/Engineering and Management, Vol 129, No 2, p 44, 46, 47, February, 1982. 3 Fig, 6 Ref.

Descriptors: *Wastewater treatment, *Screens, Filters, Filtration, *Suspended solids, Design criteria, Hydraulics, *Separation techniques.

Microscreening is a physical straining process used for separation of solids from a liquid suspension by means of the liquid's passage through a porous membrane, defined as the screening or filtering medium. Separation occurs through the retention of solids, either directly by the screen or indirectly by capture of the biomat formed on the screening medium. The microscreen consists of a screening medium attached to the periphery of a rotating horizontal drum. While several studies have been made to establish those criteria which affect the hydraulic design of a microscreen, several significant principles are frequently omitted, foremost among which has been the net effective screening

LIBRARY U. OF L. URBANA-CHAMPAIGN

area and headloss capability associated with various screening medium mounting concepts. For conventional microscreen applications including the polishing of a secondary effluent, microscreen design has been based on hydraulic loading criteria, defined in terms of gpm/sq ft of nominal submerged surface area. Field research for the development of process technology in the newest microscreening application, algae removal from lagoons, ponds and stabilization basins, led to the establishment of hydraulic loading results in terms of gpm/ft of net effective submerged surface area. The traditional screening media mounting concept employs a fine screening medium backed up by a coarse, typically 10 or 20 mesh screen. The screening grid is an innovative mounting concept consisting of a single screen integrally cast into an 18 by 24 in polypropylene grid with the medium supported on 1 in centers by grid rib framework. Suspended solids removal efficiencies of 70-90% are achievable when operating at a headloss up to 15 in. (Baker-FRC)

A LOW-COST SECONDARY TREATMENT ALTERNATIVE,
Clemson Univ., SC. Dept. of Environmental Systems Engineering.
L. G. Rich.
Water/Engineering and Management, Vol 129, No 2, p 27-28, February, 1982. 4 Fig, 2 Tab.

Descriptors: *Secondary wastewater treatment, *Aerated lagoons, Lagoons, Wastewater treatment, *Wastewater facilities, Activated sludge processes, Sludge, *Economic aspects.

A low-cost alternative to high-maintenance, mechanically complex secondary wastewater treatment systems is provided by dual-power level, multicellular aerated lagoon systems. These systems will discharge effluents low in both suspended solids and biochemical oxygen demand. Such systems consist of a first cell in which sufficient aerator power is applied to maintain all organic solids in suspension. It is followed by a series of cells, each of which is aerated at power levels that permit the settleable fraction of the suspended solids in the effluent from the first cell to settle. The concept of the dual-power level, multicellular system has been followed in the upgrading of existing faculative lagoon systems. One such system is located in a subdivision of Columbia, South Carolina. Preliminary performance data indicate that after the upgrading had been completed, only one BOD5 reading and no total suspended solids readings exceeded 30 mg/l. Most of the values were less than 20 mg/l. A typical activated sludge system where land disposal is practiced provides for conversion of wastewater components to biomass, solids separation, solids stabilization and solids storage. This last step is needed to accommodate the seasonal nature of land disposal. A dual-power level multicellular aerated lagoon system, the solids from which are also disposed of on land, is descriped. This simpler lagoon facility provides for all the steps listed above for the activated sludge system. The advantages held by the dual power level multicellular aerated lagoon systems are primarily economic. The greatest disadvantage is the lack of control over system operation. (Baker-FRC)

VIRGINIANS OPTIMIZE SLUDGE HANDLING,
Lynchburg Regional Wastewater Treatment Plant, VA.
M. H. Thomas.
Water/Engineering and Management, Vol 128, No 12, p 36, December, 1981. 1 Fig.

Descriptors: *Sludge, *Wastewater treatment, *Cost-benefit analysis, *Suspended solids, *Sludge cake, Economic aspects, Rainfall, Land disposal, Effluents, Sludge drying, Sludge thickening, Operating policies, Operating costs, Dewatering, *Lynchburg, Virginia.

The Lynchburg regional wastewater treatment plant in Virginia is described. It serves approximately 70,000 people. It incorporates a thermal conditioning section for the treatment and dewatering of sludge, and it also treats wastes of a paper board mill. By manning and running the thermal conditioning unit on a 24 hour schedule Monday through Friday, several economies have been achieved. Among these are savings on gas, electricity, maintenance, and personnel. In addition, transport costs are saved by eliminating week-end truck services. (Titus-FRC)

REMOVAL OF REFRACTORY ORGANICS FROM WATER BY AERATION. I. METHYL CHLOROFORM,
Vanderbilt Univ., Nashville, TN. Dept. of Chemistry.
T. Lionel, D. J. Wilson, and D. E. Pearson.
Separation Science and Technology, Vol 16, No 8, p 908-935, September, 1981. 22 Fig, 4 Tab, 38 Ref.

Descriptors: *Water treatment, *Aeration, Wastewater treatment, Model studies, Mathematical models, *Methyl chloroform, Chloroform, *Organic compounds, Industrial wastes.

A straightforward mathematical model is presented of an aerator apparatus used for removing volatile organics with a supernatant nonvolatile organic liquid layer. The dependence of the model's output on the physical parameters describing the system being modeled is investigated. Data on the removal of 1,1,1-trichloroethane are reported and used as a test of the mathematical model. The agreement between the observed results and the calculated curves is fairly good. The major discrepancies appear to be associated with uncertainties in the gas chromatographic analysis and with the decrease in temperature during the initial stages of the runs. These data are believed to support the mathematical model. It is noted that the only parameter in the model which is adjustable is the mass transfer rate coefficient. The experimental results are encouraging in terms of the application of the technique for wastewater and drinking water treatment. As an example, it was estimated that 3.39 volumes of air per volume of water removes about 91% of the trichloroethane when the air flow rate is 120 mL/min. At an air flow rate of 60 mL/min, 3.39 volumes of air per volume of water removes about 92% of the trichloroethane. The situation is not so favorable in the case of chloroform, since about 6.0 volumes of air are needed to remove 90% of the chloroform from water with this apparatus. The findings demonstrate the importance of having fairly small bubbles and long columns, which provide large bubble surface-to-volume ratios and long bubble-water contact times, both of which favor increased mass transfer. Solvent sublation is also able to remove nonvolatile materials from water, provided that they are surface-active. (Baker-FRC)

MICROBIAL REMOVAL OF HAZARDOUS ORGANIC COMPOUNDS,
Sohio Research Center, Cleveland, OH.
H. Kobayashi, and B. E. Rittmann.
Environmental Science and Technology, Vol 16, No 3, p 170A-138A, March, 1982. 6 Fig, 3 Tab, 151 Ref.

Descriptors: *Hazardous materials, *Biodegradation, Bacteria, Anaerobic bacteria, *Organic compounds, Degradation, *Wastewater treatment, Fungi, Actinomycetes.

Many microorganisms not previously considered useful for biological waste treatment could be applied to the removal of anthropogenic substances within certain broad limitations. Biological treatment can in numerous cases eliminate hazardous compounds by biotransforming them into innocuous forms, degrading them by mineralization to carbon dioxide and water, or anaerobically decomposing them to carbon dioxide and methane. In contrast to naturally occurring compounds, manmade compounds are relatively refractory to biodegradation. Many environmentally important man-made compounds are halogenated, and halogenation is often implicated as a reason for persistence. Examples of biological reductive dehalogenation are well documented. Specific groups of organisms that may be useful for treating specific types of man-made compounds are briefly discussed, including actinomycetes, fungi, bacteria, phototrophic microorganisms, anaerobic bacteria, and oligotrophic bacteria. The major issues which must be considered in attempts to improve biological treatment by use of selective types of organisms are population selection, development and retention. (Baker-FRC)

INFLUENCE OF TEMPERATURE ON THE ANAEROBIC ACIDIFICATION OF GLUCOSE IN A MIXED CULTURE FORMING PART OF A TWO-STAGE DIGESTION PROCESS,
Amsterdam Univ. (Netherlands). Lab. of Chemical Technology.
R. J. Zoetemeyer, P. Arnoldy, A. Cohen, and C. Boelhouwer.
Water Research, Vol 16, No 3, p 313-321, March, 1982. 11 Fig, 4 Tab, 35 Ref.

Descriptors: *Sludge digestion, *Temperature effects, Activated sludge process, Anaerobic conditions, *Anaerobic digestion, Biodegradation, Digestion, Anaerobic bacteria, Bacteria, Glucose.

The anaerobic acidification of a 1% glucose monohydrate containing medium was studied with respect to maximum dilution rate and product distribution over the temperature range of 20 to 60 degrees C. A Continuous Flow Stirred Tank Reactor inoculated with activated sludge was used for the study, allowing carbon limited growth of microorganisms. A mesophilic and a thermophilic region could be distinguished, with optimum temperatures of 37 degrees C at a dilution rate maximum of 0.51/hour and 52 degrees C with a maximum dilution rate of 0.71/hr. Optimal sludge loadings were 77 and 112 kg chemical oxygen demand/day. The gas phase consisted of carbon dioxide and hydrogen, and yield values ranged between 13.5 and 18.0% as the temperature was varied from 25 to 55 degrees C. Deviations were obtained at lower and higher temperatures. In the liquid phase, mainly acetate, propionate, butyrate, lactate and ethanol were found. Product distribution at the maximum loading rates was fairly constant in the mesophilic range, but was markely variable in the thermophilic range. Product distribution also was highly dependent on sludge loading except at high loadings. Separate acidification should be designed at mesophilic temperature below optimal temperature and at high, almost maximal sludge loadings. (Baker-FRC)

EXPERIENCES WITH PURIFICATION LAKES AND POLISHING LAGOONS,
Ruhrverband, Essen (Germany, F.R.).
K. R. Imhoff.
Water Science and Technology, Vol 14, No 1/2, p 189-204, 1982. 16 Fig, 3 Tab, 11 Ref.

Descriptors: *Lakes, *Lagoons, *Tertiary wastewater treatment, Self-purification, Wastewater treatment, Ruhr River, *Germany, Wastewater lagoons, Sediment, Lake sediment, Effluents, Lake Kemnade, Lake Hengstey, Lake Kettwig, Lake Baldeney, Lake Harkort, Recreation, Algal growth, *Ruhr Valley.

Purification lakes and polishing lagoons have been successful in tertiary treatment of wastewater in the Ruhr Valley, Federal Republic of Germany. A series of 5 lakes, built along the river starting in 1929, provide low-cost primary and secondary effluent polishing as well as stormwater treatment. After 40-50 years of operation the lakes have accumulated millions of cu m of sludge, containing high concentrations of phosphate and heavy metals. In 1982 this sediment will be dredged from the river bed and placed in lagoons for dewatering and drying. Polishing lagoons have also been built to further treat effluents from older trickling filter and activated sludge plants. Generally the required 20 mg per liter BOD and 100 mg per liter COD are attained with 1-2 days retention time. An average of 55% of BOD and 31% COD are removed in

this manner. Suggestions for design and operating of lagoons are: 2 days retention time, 1-2 meters depth, ponds in series with gravel beds serving as overflows into the next pond, no lining to allow percolation, and removal of sludge as necessary. The lakes and ponds are desirable for recreation and wildlife observation. (Cassar-FRC)

NITROGEN CONTROL FOR THE PARTLY SEWERED BASIN OF YODO RIVER-LAKE BIWA SYSTEM,
Kyoto Univ. (Japan).
S. Iwai.
Water Science and Technology, Vol 14, No 1/2, p 215-225, 1982. 7 Fig, 7 Ref.

Descriptors: *Nitrogen removal, *Eutrophication, *Aeration, Wastewater treatment, *Yodo River, Lake Biwa, *Japan, Phosphorus removal, Model studies, Water pollution sources, Phytoplankton, Nitrification, Denitrification, Faculative denitro-aeration process, Water quality, Water pollution effects.

Water quality in the downstream reaches of the Yodo River and in Lake Biwa, Japan, has deteriorated so that their use as water supplies for 13 million inhabitants is threatened. Sources of pollution in this watershed are nightsoil, lack of sewage treatment, industries, livestock rising, and farming. A simulation process is developed for eutrophication of lake water and applied to Lake Biwa, with good agreement between calculated and observed data. Faculative Denitro-Aeration (FDA) is described for treatment of nightsoil. This consists of simultaneous BOD removal, nitrification, and denitrification with mixed liquor recycle; sedimentation with sludge recycle; nitrification followed by denitrification using methanol as a carbon source; flush aeration; and sedimentation. Recycling distances are very short. The FDA process consumes little power for pumping and can tolerate mixed liquor suspended solids up to 12,000 mg per liter. Removal rates reach 95% BOD5, 90% COD, and 95% total N. This method, with modifications, was used at the Hikone nightsoil plant to produce potable water with no coliforms, 0.4 mg per liter BOD5, 3.7 mg per liter COD, less than 1 mg per liter suspended solids, 3.46 mg per liter total N, 0.41 mg per liter total P, and 180 mg per liter chloride. SINGLE SLUDGE NITROGEN REMOVAL FROM INDUSTRIAL WASTEWATER,
AWARE Corp., Nashville, TN.
Y. Argaman.
Water Science and Technology, Vol 14, No 1/2, p 7-20, 1982. 4 Fig, 3 Tab, 11 Ref.

Descriptors: *Industrial wastewater, *Nitrogen removal, *Activated sludge process, Wastewater treatment, Nitrification, Denitrification, Biological treatment, Ammonium, Nitrates, Kinetics, Single sludge process.

The single sludge nitrification-denitrification process is described and compared with the two-sludge system. The single sludge process does not require an external carbon source, needs less oxygen and neutralizing chemicals, but may use more pumping energy, depending on the wastewater composition. The design procedure developed in this paper uses zero order kinetics for nitrogenous substrates removal and first order kinetics for carbonaceous organics removal. Trial and error calculations yield a solution. In industrial wastewater applications acid-base equilibria are significant. Inhibition of nitrification and denitrification takes place at both high and low pH levels. Free ammonia is inhibiting at high pH and free nitrous acid at low pH. Nitrification destroys alkalinity, and denitrification forms alkalinity. A bench-scale continuous flow run of an amino acid industrial wastewater containing 6360 mg per liter BOD and 1625 mg per liter total Kjeldahl nitrogen (TKN) produced an effluent with 24 mg per liter BOD and 265 mg per liter TKN. Full-scale operations of a ditch-type system using a combined pharmaceutical-pesticides-herbicides wastewater (influent BOD 800-1100 mg per liter, ammonia-N 32-126 mg per liter) produced a good quality effluent (8-13 mg per liter BOD, 0-18 mg per liter ammonia-N, and 2-7.2 mg per liter nitrate). HOW THE TYNE WAS SAVED. DUKE OF EDINBURGH OPENS 120 MILLION POUND STERLING SCHEME.
Water and Waste Treatment, Vol 24, No 12, p 22-24, December, 1981. 5 Fig.

Descriptors: *Wastewater treatment facilities, *Design considerations, Wastewater treatment, Construction, *Tyne River, Rivers, England, Hydrogen sulfide, Sludge, Activated sludge process, Primary wastewater treatment, *Odor control.

An innovative manner of dealing with hydrogen sulfide emissions at the Tyneside Sewage Treatment Scheme involves the measured introduction of oxygen. The plan has attracted considerable international interest, as have the remote monitoring arrangements for the sewers and the treatment works of this scheme. Twenty-five miles of interceptor sewers have been built, out of the eventual total of 45 miles, and now most of the main sewers on both banks of the east of the Tyne Bridge section are completed. The total length of sewers in the completed scheme will be about 75 km, varying in internal diameter between 0.45 and 3 meters. The system is designed so that most of the sewage flows by gravity, but in some places pumping stations have had to be built to lift the sewage from low lying areas. Primary treatment is expected to be sufficient to maintain the Tyne estuary in a healthy state, but if the sewage load should increase or a higher standard of river water quality is needed in the future, enough land is available on the site for further treatment. CONTAINMENT AND TREATMENT OF THE LOVE CANAL LANDFILL LEACHATE,
Niagara Falls Wastewater Treatment Plant, New York.
W. J. McDougall, R. A. Fusco, and R. P. O'Brien.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2914-2924, December, 1980. 7 Fig, 7 Tab, 4 Ref.

Descriptors: *Landfills, *Leachates, *Organic compounds, *Activated carbon, Priority pollutants, Wastewater treatment, Adsorption, *Love Canal, *New York, Path of pollutants, Chemical wastes, Chlorinated hydrocarbons.

The leachate containment and collection system built at the Love Canal chemical landfill site near Niagara Falls, New York are described. At this site, rainwater entered the top layer of permeable soil, carrying contaminants laterally. In the southern sector of the dump area an impervious clay cap was constructed to minimize surface water entrance. A perimeter drain tile collection system of 8 inch perforated pipe, 10-15 ft deep, carried the leachate to pumping stations, where the contaminated water was fed to an activated carbon treatment system. The temporary 2-stage adsorption system installed held a full truckload of 20,000 pounds of granular carbon in each vessel and processed 175 gal per min of wastewater. Spent carbon was transferred to an empty truck for reactivation at another site, and the empty vessel was refilled with a fresh truckload of carbon. All carbon transfers were handled in a closed system to prevent workers' exposure to the spent carbon. Assessment of the treatment showed a removal rate of nearly 100% for some of the 80 organic compounds identified in the leachate. Only 67% of the methylene chloride was removed. A permanent carbon system was started up in December 1979. This has continued to operate satisfactorily according to specifications. (Cassar-FRC)

PERFORMANCE OF A LARGE ADVANCED WASTE TREATMENT PLANT,
Alvord, Burdick and Howson, Chicago, IL.
D. E. Eckmann, and H. S. Zimmerman.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2717-2725, November, 1980. 7 Fig, 3 Tab.

Descriptors: *Wastewater treatment, *Evaluation, Advanced wastewater treatment, *Wastewater facilities, Reservoirs, Eutrophication, Water pollution sources, *Water pollution prevention, Roanoke, *Virginia, *Smith Mountain Lake.

A dam was built on the Roanoke River to create Smith Mountain Lake in southwest Virginia in the 1960s. This lake is one of the finest recreational reservoirs in southwest Virginia. The state determined that the Roanoke Sewage Treatment Plant, which is located upstream from the dam, had to be upgraded to control eutrophication of the lake. A 132 M1/d advanced wastewater treatment plant was built for about $28 million, and has been in operation for more than one year. It has at times treated flows of over 227 M1/d (60 mgd) and on an annual average has produced the following quality effluent: biochemical oxygen demand 1.8 mg/1, suspended solids 0.8 mg/1, phosphorus 0.1 mg/1, total Kjeldahl nitrogen 0.2 mg/1, and fecal coliforms 2.8/100 ml. The plant consists of the activated sludge process followed by nitrification, flocculation, coagulation, filtration, and disinfection facilities. The quality of the effluent under average and maximum conditions, the effect of each process upon the overall treatment, amount of sludge generated, chemicals used, and other major parameters of each process are presented with special emphasis on filtration as well as construction and operating costs. SHOCK LOAD OF CHROMIUM (VI),
Mankato State Univ., MN.
R. C. Henney, M. C. Fralish, and W. V. Lacina.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2755-2760, November, 1980. 1 Fig, 1 Tab, 18 Ref.

Descriptors: *Chromium, *Activated sludge process, Sludge, *Wastewater treatment, Industrial wastewater, Biological wastewater treatment, Microorganisms, Bacteria, Chemical spills, Electroplating.

A spill of about 227 kg of chromium(VI) from a slowly overflowing electroplating tank into the collection system of the Mankato, Minnesota 38,000 cubic meter/day (10 mgd) activated sludge plant occurring on October 23-24, 1977, precipitated this study. Automatic samplers at the wastewater treatment plant sampled the influent and effluent before, during, and after the spill along with additional grab samples from various plant units. The greatest effect of the chromium(VI) on the activated sludge process was seen in the aeration tanks, where the activity of the organisms was severely, but only temporarily, depressed. The greater part of the shock load of chromium(VI) passed through the plant with the wastewater. Chromium(VI) was removed by wastewater treatment processes only to the extent that it was reduced to chromium(III), a process

LIBRARY U. of I. URBANA-CHAMPAIGN

that depended on the concentration of dichromate as well as the acidity and the concentration of reducing substances. Chromium(III), being insoluble at the normal acidity range of the wastewater, remained largely in the plant adsorbed onto the sludge particles, but in moderate amounts was apparently not harmful either to the processes in the aeration tank or to those in the digesters. Since the chromium(III) ended up in the finished sludge, the disposal of the sludge must be monitored. (Baker-FRC)

NITRIFICATION IN THE SEQUENCING BATCH BIOLOGICAL REACTOR,
Maryland Univ., College Park. Dept. of Civil Engineering.
J. E. Alleman, and R. L. Irvine.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2747-2754, November, 1980. 8 Fig, 2 Tab, 20 Ref.

Descriptors: *Nitrification, *Biological wastewater treatment, *Wastewater treatment, *Sludge, Bacteria, Nitrates, Oxidation, Acidity.

Studies were conducted to demonstrate the potential of the sequencing batch reactor to maintain combined organic carbon oxidation and nitrification. Using a synthetic, high-strength waste input, a bench-scale sequencing batch reactor (SBR) consistently discharged a good quality effluent, with 98+% oxidation of both the organic carbon and nitrogen components. A high quality discharge was maintained over a 2 month period. Sludge settleability was extremely good, producing a clear effluent with suspended solids averaging 6 mg/l. Sludge Volume Index measurements remained steady at 85 to 95. There was no indication of the pin floc and/or transient settling abnormalities that have been known to plague the low loading FCSTR-nitrification systems. Sequential exposure to periods of reduced oxygen tension had no apparent effect on the activity of the nitrifying bacteria. A depression in alkalinity did occur during the nitrification period, although the extent of the reduction was markedly less than the stoichiometric rate based on proton release through ammonium ion oxidation. Overall, the sequencing batch reactor unequivocally demonstrated a capacity for combined oxidation of organic carbon and nitrogen. The SBR design also provided a unique opportunity to follow the metabolism of the substrate species during the React phase. (Baker-FRC)

A SURVEY OF PHOSPHORUS REMOVAL IN LOWER GREAT LAKES MUNICIPAL TREATMENT PLANTS,
Clarkson Coll. of Technology, Potsdam, NY. Dept. of Civil and Environmental Engineering.
M. S. Switzenbaum, J. V. DePinto, T. C. Young, and J. K. Edzwald.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2628-2633, November, 1980. 3 Fig, 5 Tab, 8 Ref.

Descriptors: *Effluent limitations, *Phosphorus removal, *Great Lakes, *Municipal wastewater, *Chemical coagulation, Phosphorus, Water quality standards, Lakes, Wastewater treatment, Surveys, Water quality control, Chemical treatment, Lake Erie basin, Lake Ontario basin.

A questionnaire was sent to 229 municipal wastewater treatment plants in the Lake Erie and Lake Ontario basins with effluent flows greater than 3,785 cu m/day. Results of the survey showed that the approach most commonly used to comply with the 1978 Great Lakes Water Quality Agreement for phosphorus was the addition of iron or aluminum salts to the wastewater during secondary treatment. Currently 52% of the treatment facilities surveyed have effluent total P levels of less than or equal to 1.0 mg/l. Total P loadings to the two lakes were determined. It was estimated that a 0.5-mg/l P effluent standard alone would not be sufficient to achieve the International Joint Commission target loads of 11,000 and 7,000 metric tons/year for Lake Erie and Lake Ontario, respectively. RELATIVE HEALTH RISKS OF ACTIVATED SLUDGE TREATMENT AND SLOW-RATE LAND TREATMENT,
Metcalf and Eddy, Inc., Palo Alto, CA.
A. Uiga, and R. W. Crites.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2865-2874, December, 1980. 12 Tab, 24 Ref.

Descriptors: *Risks, *Land application, *Activated sludge process, Public health, Wastewater treatment, Wastewater irrigation, *Wastewater disposal, Lagoons, Aerosols, Viruses, Bacteria, Pathogens, Metals, Organic compounds, Sludge treatment, Sludge disposal.

The potential health effects of two wastewater treatment systems--activated sludge with effluent discharge to surface water and slow-rate land application-- are compared. Evaluation considers contact intensity (physical, aerosol inhalation, accidental ingestion, and potable ingestion) and contact duration. Both systems, if properly maintained, minimize health risks. Slow-rate land treatment offers greater protection against parasites and viruses, trace metals, nitrates, and trace organics and is less susceptible to process upsets. Workers at treatment facilities may be exposed to infectious agents via aerosol inhalation and incidental contact, but the health risks are no greater than for the general public. Wastewater irrigation of non-food crops is safer than irrigation of food crops. Health hazards from trace metals and trace organics are difficult to evaluate. Some of the differences in health risks are a result of the high concentration of the sludge versus the more dilute and more widely dispersed wastewater applied to land. (Cassar-FRC)
W82-05258

ION-PRECIPITATE FLOTATION OF IRON-CYANIDE COMPLEXES,
International Nickel Inc., Sterling Forest, NY.
R. O. Bucsh, D. J. Spottiswood, and G. W. Lower.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2925-2930, December, 1980. 7 Fig, 1 Tab, 8 Ref.

Descriptors: *Cyanide, *Metal-finishing wastes, *Flotation, Surfactants, *Wastewater treatment, Iron compounds, Ferrocyanide, Ferricyanide, *Separation techniques.

Removal of cyanide, ferrocyanide, and ferricyanide ions from wastewaters was accomplished by an ion-precipitate flotation process. Tricaprylmethyl ammonium chloride, a surfactant, combined with cyanide ions to form a waxy material. This substance rose to the surface during air flotation. Average recoveries of the three ions were: cyanide, 28%; ferrocyanide, 73%; and ferricyanide, 71%. Process variables were studied, using ferricyanide for most experiments. Recovery of ferricyanide increased with surfactant dosage to 1.25 times the stochiometric amount of surfactant. Chloride ion decreased the critical micelle concentration; up to 1.5 stochiometric multiples of surfactant, more ferricyanide was removed without chloride than in the presence of chloride. Removal decreased with feed flow rate increases up to about 500 ml per min, and became constant at higher flow rates. An air flow rate above 3 liters per min caused a sharp drop in removal of ferricyanide. Ferricyanide at concentrations < 15 ppm was poorly removed because wax moelcules were too few to agglomerate and float. The concentration-recovery curve leveled off at about 30 ppm. Although pH slightly decreased removal at pH 7-10, recovery was acceptable over the range 4-10 pH. (Cassar-FRC)
W82-05259

CONTROL OF SLUDGE BULKING IN THE BREWING INDUSTRY,
Sverdrup and Parcel and Associates, Inc., St. Louis, MO.
H. G. Schwartz, Jr., T. Popowchak, and K. Becker.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2977-2993, December, 1980. 11 Fig, 6 Tab, 16 Ref.

Descriptors: *Fermentation, *Sludge bulking, *Process control, Wastewater treatment, Industrial wastewater, *Activated sludge process, Carbohydrates, Shock loads, Organic loading, Dissolved oxygen, Oxygen, Nutrients, Chlorination, Hydrogen peroxide, Oxidation, *Brewing industry.

The Miller Brewing Company wastewater treatment plant at Fulton, New York, suffered two extended periods of filamentous sludge bulking and solids loss during the first two years of operation. These incidents (September 1976 to February 1977 and November 1977 to April 1978) presented opportunities for evaluating control methods. The single most cirtical factor in maintaining a healthy mixed microbial population was adequate dissolved oxygen, no less than 2 mg per liter, throughout the aeration basin. In addition, nitrogen, phosphorus, and possibly iron were essential nutrients. The activated sludge system, operating with variable strength, high carbohydrate wastes, required careful monitoring and control to equalize waste loads. On one occasion a shock load of caustic cleaning solution and disinfectants destroyed the microbial population. A plant information program was prepared to educate plant personnel about the harmful effects of shock loads and toxic substances. When settleability dropped and sludge blankets rose, immediate treatment with 10-20 mg per liter cationic polymers allowed restabilization. Chlorination and hydrogen peroxide additions were ineffective in reducing sludge bulking at this plant. Since conditions that lead to sludge bulking take several weeks to develop, corrective measures ususally requie several weeks to be effective. Since the latest recovery period, effluents from the treatment plant have met discharge permit standards. (Cassar-FRC)
W82-05260

ULTRA-HIGH-RATE FILTRATION OF RAW AND COMBINED SEWER OVERFLOWS,
Environmental Protection Agency, New York.
H. Innerfeld, and D. Ruggiero.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2931-2945, December, 1980. 2 Fig, 12 Tab, 1 Ref.

Descriptors: *Combined sewer overflows, *Filtration, *Wastewater treatment, High rate filtration, Suspended solids, Biological oxygen demand, Chemical oxygen demand, Alum, Polyelectrolytes, Settleable solids, Backwash, *Newton Creek Water Pollution Control Plant, *New York City.

Combined sewer overflows (CSO) and raw dry weather wastewater flows (RDWWW) were treated by ultrahigh-rate filtration at a pilot plant located in New York City's Newtown Creek Water Pollution Control Plant. The 760 mm diameter filter column contained 1.5 m of No 3 anthracite above 760 mm of No 612 sand on a 460 mm gravel base. CSO treatment at 11 liters per sq m per sec removed suspended solids at an average of 62% across the filter and 66% across the system. BOD removals were 32% and COD removals 40%. Polymer and alum additions improved removals to 38% for BOD and 50% for COD. Treatment of RDWWW at 5.4 liters per sq m per sec produced suspended solids removals of 67% across the filter and 70% across the system, BOD removals of 33%, and COD removals of 32% across the filter. Addition of polymers improved performance to 39% for BOD and 34% for COD at flow of 8.1 liters per sq m per sec. Use of polymers plus alum did not improve filtration further. Since % removals of suspended solids are dependent on the strength of influent flows, the filtration system should be rated on the basis of total solids captured per unit filter area. This should be at least 15.1 kg per sq m for RDWWW and 22.0 kg per sq m for CSO. Settleable solids were removed to an extent of 95% or greater, but dissolved materials were not removed. (Cassar-FRC)

MATHEMATICAL MODEL OF SEQUENTIAL LOADING IN FIXED-BED ADSORBERS,
Michigan Technological Univ., Houghton.
J. C. Crittenden, B. W. C. Wong, W. E. Thacker, and R. L. Hinrichs.

Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2780-2795, November, 1980. 5 Fig, 1 Tab, 43 Ref.

Descriptors: *Model studies, *Adsorption, *Wastewater treatment, Mathematical models, Water treatment, Water quality, Organic compounds, Adsorbents.

This work is part of a continuing effort to develop a model that accurately predicts the organic removal efficiency of fixed-bed adsorption systems. The model will be useful to the design engineer in the designing of adsorbent systems which minimize the possibility of chromatographic desorption of weakly adsorbed toxics, in the selection of adsorber design likely to yield the best quality effluent at the least cost, and in the selection of adsorbents based on relatively simple and quick batch tests. The focus of the study was on the development of a model able to predict displacement or chromatographic effects. The model described predicts the concentration history profiles of binary mixtures with time-variant influent feed conditions. Mass balance relationships within the column in the axial direction and within the adsorbent particles in the radial direction that incorporate Fick's Law for the intraparticle surface diffusion flux and film transfer for the liquid-phase diffusion flux were the conceptual basis of the model. Orthogonal collocation was used to solve the model equations. Model predictions were compared to column data for these two time-variant influent conditions: the non-key component was fed until the adsorber was exhausted and then both adsorbates were fed until the adsorber was exhausted with respect to the key component; and the reverse loading order. These comparisons represented a verification of the model for sequential influent loadings and for single solute adsorption because good agreement between model predictions and data was found and because parameters used in the model were obtained from independent tests. PHOSPHORUS AND NITROGEN REMOVAL AT CADILLAC, MICHIGAN,
Ayres, Lewis, Norris and May, Inc., Ann Arbor, MI.
A. K. Singhal.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2761-2770, November, 1980. 7 Fig, 8 Tab, 6 Ref.

Descriptors: *Wastewater treatment, *Water pollution control, Phosphorus, *Phosphorus removal, *Nitrogen removal, Suspended solids, Alkalinity, Acidity, Advanced wastewater treatment, *Cadillac, Michigan.

The advanced wastewater treatment at the Cadillac, Michigan treatment facility all but eliminates pollution to the receiving stream, the Clam River, thus allowing recreational use of the waters without endangering public health. The plant is able to meet stringent state and federal treatment requirements with overall removals of greater than 97% biochemical oxygen demand (BOD), 96% suspended solids (SS), 92.5% ammonia nitrogen, and 80% phosphorus. Experience at the plant indicates that an aeration system can be effectively used for phosphorus removal provided the air quantity after addition of ferric chloride or alum is properly adjusted to provide velocity gradients of around 50/sec. Equations are presented which can be used to estimate the air requirements for any given plant. The design of an aeration system piping should make provisions for monitoring the air input into the portion of the system being used for phosphorus removal by using air-flow metering devices. Attached biological growth systems using rotating biological contactors (RBC) can be successfully used for ammonia nitrogen removal from secondary effluent. Consistent BOD and SS removal are obtained by using rapid sand filters at the end of the RBC units. There does not appear to be a need for a clarifier between the RBC and tertiary sand filters in a system treating secondary effluent. Design of a nitrification system should take into account the impact of various parameters such as alkalinity of the influent wastewater and impact of ammonia nitrogen loading and provide for potential accumulation of heavy metals in the attached growth systems. (Baker-FRC)

COMPREHENSIVE ANALYSIS OF NITRIFICATION OF CHEMICAL PROCESSING WASTEWATERS,
Engineering-Science Inc., Austin, TX.
D. L. Ford, R. L. Churchwell, and J. W. Kachtick.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2726-2746, November, 1980. 16 Fig, 4 Tab, 33 Ref.

Descriptors: *Industrial wastewater, *Nitrification, Chemical analysis, Ammonia, *Wastewater treatment, *Biological processes, Microorganisms, *Huston, Texas.

To determine the feasibility of enchancing biological nitrification of the wastewater discharged from the Tenneco Chemicals plant in Houston, Texas, a series of comprehensive bench-scale treatability studies was undertaken. Throughout the program an extensive effort was made to isolate and quantify Nitrobacher and Nitrosomonas. The fraction of viable bacteria that these autotrophs represented in the mixed liquor was then correlated with specific system variables such as ammonia-nitrogen loading, resultant-fee ammonia and free nitrous acid concentrations and specific ammonia removal. The study was divided into two parts. In the first part a control reactor with an aeration and side-stream reaeration system evaluation was used. The second study concerned a control reactor with a two-stage aeration system evaluation. Biological nitrification did not change organic removal capacity of the biological reactors. Data showed that free ammonia concentrations of 30 mg/l or higher may be inhibitory to Nitrosomonas. Free nitrous acid concentrations from 0.28 to 1.0 mg/l tended to inhibit Nitrobacher, resulting in nitrite accumulation. (Baker-FRC)

USE OF BENCH-SCALE DIGESTERS TO EVALUATE FULL-SCALE DIGESTER PERFORMANCE,
C. M. Engineering Associates, Vista, CA.
J. S. Murk, J. L. Frieling, L. D. Tortorici, and C. C. Dietrich.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2709-2716, November, 1980. 8 Fig, 2 Tab.

Descriptors: *Digestion, *Evaluation, *Wastewater treatment, Wastewater facilities, *Anaerobic digestion, Laboratory studies, Performance evaluation, Monitoring, *Encina Water Pollution Control Facility, California.

A large municipal wastewater treatment plant in Southern California was used to demonstrate the reliability and accuracy of laboratory scale pilot digesters to duplicate and predict the performance of full scale anaerobic digester. Three 28 liter bench scale digesters were fabricated and operated at the Encina Water Pollution Control Facility, a 52,040 cubic meter/day regional wastewater treatment plant in North San Diego County, to help overcome a chronic operational problem with foaming digesters. These bench scale anaerobic digestion studies have afforded an economical, reliable, and simple approach to determining the causes for digester foaming. By this inexpensive technique, design and operational changes have been implemented, providing improved digester performance and unhampered operation. Properly designed laboratory scale digesters can greatly assist in controlling and maintaining anaerobic digester performance and determining at little cost the reasons for process inefficiencies. Descriptors: *Heavy metals, *Membrane processes, *Wastewater treatment, Chelation, *Chelating agents, *Ultrafiltration, Charged membrane ultrafiltration, Donnan Exlusion, Rejection model, Complex species, EDTA, Oxalates, Cyanide, Zinc, Copper, Cadmium, *Separation techniques.

The rejection behavior of heavy metals was established in the presence of complexing agents, utilizing negatively charged ultrafiltration membranes. An extensive experimental investigation was conducted with Zn, Cd, and Cu, in the presence of cyanide, ethylenediamine tetraacetic acid, and oxalates, under insignificant concentration polarization condition. The rejection dependence of the heavy metals was found to be a function of feed metal concentration, metal types, complexing agent to metal feed molar ratio, pH and ionic strength. The dependence of rejection behavior of heavy metals and complexing agents on pH concentration is explained in terms of metal complex species distribution and Donnan Exclusion model. For EDTA and oxalate systems, the rejections of metal are independent of initial metal concentration; whereas for the cyanide system the rejections of both metal and cyanide decrease with concentration. At transmembrane pressure of 5.6 x 10 to the fifth power N/sq m, metal rejections range between 77% and 96%. For all cases, the rejection of metal is highly dependent on the size and charge of the complex metal species.

FILTRATION PERFORMANCE IN WATER AND WASTEWATER TREATMENT: THEORY AND MEASUREMENT,
Wright-Pierce Architects/Engineers, Portsmouth, NH.
J. E. Tobiason, and C. R. O'Melia.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224627, Price codes: A07 in paper copy, A01 microfiche. Report No 172, March 1982, 110 p, 28 Fig, 5 Tab, 60 Ref. 2 Append. OWRT A-104-NC(2), 14-34-0001-9035.

Descriptors: Sand filters, Soil filters, Mathematical models, *Filter performance, *Flocculation, *Filtration, Filter media, Filter rate, *Wastewater treatment, *Particle size, Granular filter, Filter theory, Filter ripening.

An earlier model for filter ripening, designed to predict changes in effluent quality and head loss with time as filtration proceeds, was extended and applied. Reasonable agreement was found between observed and predicted filtrate quality. Head loss predictions are quantitatively similar to observations but are generally lower. Suspensions containing small particles produce more head loss than suspensions of larger particles when the comparison is based on equivalent masses of solids removed by the filters. Particles smaller than a few microns in size are particularly troublesome in this regard. This indicates that flocculation prior to filtration is important when direct filtration is considered, particularly when submicron sized particles are to be treated. Additional important effects have been noted for the concentration of solids applied to a filter and, as noted by others, for the chemistry of the pretreatment processes. High concentrations of suspended solids are observed to produce more head loss than lower concentrations.

CHARACTERIZATION, RENOVATION, AND UTILIZATION OF WATER FROM SLURRY TRANSPORT SYSTEMS,
Missouri Water Resources Research Center, Columbia.
S. E. Manahan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224668, Price codes: A02 in paper copy, A01 in microfiche. Report, February 1982. 22 p, 10 Fig. OWRT B-145-MO(2), 14-34-0001-0228.

Descriptors: *Slurries, *Chromium, *Coal, Water exchange, *Sorption, Heavy metals, Baseline studies, Water use, Water conveyance, Water carrying capacity, Water transport, Energy sources, Resources management, Water management, Industrial water, Industrial development, Chemical properties, Corrosion control, *Wastewater renovation.

An understanding of water-solid interactions under slurry conditions is needed in order to characterize, renovate, and utilize water from slurry transport systems. To address this need, study emphasis was placed on two major considerations: water interchange between the suspending medium and the coal and coal-derived solids; and the interaction of coal and coal-derived solids with chromium (VI), or chromate, an anticorrosive agent that may be used in coal slurries. Materials used in these investigations were prepared in laboratory-scale operations from ground and sieved Wyoming subbituminous coal. Water interchange was studied in experiments using radiolabelled tritiated water. Sorptin of chromium (VI) by solids was studied in slurries containing 10 g of damp solid and 10 ml of chromate solution as a function of pH. The study results indicated that coal and coal-derived solids have a strong affinity for certain solutes in water, such as chromate, with (generally) a rapid instantaneous sorption of a fraction of the solute occurring. Water interchange study indicated that part of this rapid sorption may be due to exchange of exchangeable water in initially moist solids. The methodology employed here and the concept of exchangeable water and its dilution effect should be useful in future studies of coal-water interactions. (Zielinski-MAXIMA)

STUDIES OF NITRIFICATION IN A COKE-WASTE ACTIVATED SLUDGE PROCESS,
Alabama Univ., Birmingham. Dept. of Biology.
D. D. Jones.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224700, Price codes: A04 in paper copy, A01 in microfiche. Report, September 1981. 27 p, 8 Fig, 10 Tab, 22 Ref. OWRT A-075-ALA(2), 14-34-0001-0101.

Descriptors: *Nitrification, *Bacteria, *Activated sludge process, *Coal, *Industrial wastewater, Activated sludge, Fluorescence, Microbial degradation, Industrial wastes, Refinery wastes, Ammonia, Biodegradation, Sludge digestion, Bioassay, Biological wastewater treatment, Baseline studies.

Studies were carried out to assess the effects of environmental conditions on the activity of nitrifying bacteria in a coke-waste activated sludge process using samples of mixed liquor obtained from bench-scale reactors handling wastewater from a commercial Alabama coke plant. Using a fluorescent-antibody technique which could provide reliable estimates of the number of nitrifiers within a few hours, it was found that coke-plant mixed liquor contains about four orders of magnitude more Nitrosomonas (N) cells than shown by MPN (most probable number) estimates. It was also determined that N comprises about 2% of the total cells in the liquor at 25 day solids retention tines (SRT) or greater, and about 1% at 4.2 days SRT. Correlations between effluent ammonia and N population dynamics indicated that the ammonia removal rate in the liquor is affected by both the number of nitrifiers and the activity/cell. Experimentation using an in vitro measure of the nitrifying ability of the liquor defined the tolerance limits of nitrifiers to a variety of physical and nutritional conditions. (Zielinski-MAXIMA)

HEAT LOSS FROM RAPID INFILTRATION BASIN IN WINTER,
Minnesota Univ., Minneapolis. Dept. of Civil and Mineral Engineering.
H. G. Stefan.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE1, p 141-158, February, 1982. 7 Fig, 11 Ref.

Descriptors: *Infiltration, *Heat flow, Model studies, Basins, Groundwater, *Leaching, Percolation, Mathematical studies, Seasonal variations, Temperature effects, Economic aspects, Wastewater treatment, *Wastewater facilites.

A heat budget analysis is presented for a rapid wastewater infiltration/percolation basin to be operated at air temperatures below zero degrees C. In a rapid infiltration basin, the unchlorinated secondary effluent from a wastewater treatment plant is discharged onto the ground by flooding. Rapid infiltration basins return water to the groundwater table and provide a form of tertiary treatment. For small communities in cold climates, the year-round operation of infiltration basins without major storage requirement is economicaly attractive. The heat exchange processes associated with such a winter operation are analyzed herein with a view toward design applications. The analysis is theoretical and considers two modes of operation, one with a permanent ice cover on the basin and one without. The loading of the infiltration basin is intermittent. The analysis provides a complete heat budget. The equations are expressed in a form which permits estimation of frequency of loading of a basin as a function of loading depth. Heat losses to the atmosphere, formation of an ice cover, and cyclic freezing and thawing of the soil are included in the analysis. (Baker-FRC)

INTERNATIONAL NUTRIENT CONTROL TECHNOLOGY FOR MUNICIPAL EFFLUENTS,
Municipal Environmental Research Lab., Cincinnati, OH.
E. F. Barth, and H. D. Stensel.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1691-1701, December, 1981. 4 Fig, 8 Tab, 22 Ref.

Descriptors: *Wastewater treatment, *Phosphorus removal, *Nitrification, *Nitrogen removal, Nutrients, *Municipal wastewater, Cost analysis, Wastewater facilities.

The U.S. Environmental Protection Agency sponsored an 'International Seminar on Control of Nutrients in Municipal Wastewater Effluents' in September, 1980. This seminar reviewed nutrient control technology and needs for Canada, Japan, Sweden, Austria, Australia, Switzerland, and the United States. Design aspects, performance, operating characteristics, and costs associated with various full-scale systems for phosphorus removal, nitrification, and nitrogen removal were discussed. Chemical treatment is the most commonly used method for removing phosphorus from municipal wastewater, although biochemical and biological treatment systems are also in use. In some areas, laws requiring the use of low-phosphorus detergents reduce the costs of phosphorus removal. Full-scale nitrification systems discussed included single-stage and two-stage activated sludge nitrification systems and fixed-film processes such as plastic media trickling filters and rotating biological contactors. Full-scale nitrogen removal systems examined included oxidation ditch systems, and alternating aerobic and anoxic single-stage system, the Bardenpho system, a tertiary denitrication filter with methanol addition, a continuous-flow sequentially aerated activated sludge system, an overland flow system, and a clinoptilolite selective ion-exchange system. The capital cost and operating and maintenance costs for the facilities for removing phosphorus and nitrogen from wastewater varied over a wide range due to differences in design and operation and in effluent requirements. INHIBITION OF NITROGENOUS BOD AND TREATMENT PLANT PERFORMANCE EVALUATION,
Iowa Univ., Iowa City. Coll. of Engineering.
R. E. Dague.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1738-1741, December, 1981. 4 Fig, 3 Tab, 10 Ref.

Descriptors: *Biochemical oxygen demand, *Wastewater facilities, *Nitrification, Wastewater treatment, *Performance evaluation, Secondary wastewater treatment, Effluent standards.

The importance of considering carbonaceous and nitrogenous oxygen demands separately in evaluating the performance of wastewater treatment plants is discussed. In several cases, state regulatory agencies and/or the U.S. Environmental Protection Agency have refused to accept the inhibited (carbonaceous) 5-day biochemical oxygen demand (BOD) test as the basis for interpreting plant performance. In these cases it is difficult, if not impossible, for treatment facilities achieving partial nitrification to meet the 5-day BOD performance criteria for secondary treatment (average 5-day BOD of 30 milligrams per liter). Treatment plants which are partially nitrifying will have nitrifying bacteria associated with the volatile suspended solids in the effluent. As a result, the effluent BOD will be increased due to nitrification occurring during the standard 5-day test. Although these treatment plants would actually be removing more total BOD, they would display a higher effluent 5-day BOD than plants treating an identical wastewater but not achieving partial nitrification. It is suggested that errors resulting from the use of the standard uninhibited BOD test may result in the selection of inferior treatment processes and systems or in the penalization of treatment facilities providing superior treatment through partial nitrification. ECONOMICAL AND EFFICIENT PHOSPHORUS CONTROL AT A DOMESTIC-INDUSTRIAL WASTEWATER PLANT,
D. Van Dam.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1732-1737, December, 1981. 2 Fig, 5 Tab.

Descriptors: *Wastewater treatment, *Phosphorus removal, Wastewater facilities, *Municipal wastewater, Industrial wastewater, Activated sludge process, Operating costs, Grand Haven, Spring Lake, *Michigan.

The towns of Grand Haven and Spring Lake, Michigan, formed a combined sewer authority and began planning a new central wastewater treatment facility in 1968. The treatment plant was designed to process both domestic wastes and a substantial volume of wastewater from a chrome and vegetable tannery. The treatment plant employs grit removal, phosphorus removal, primary clarification, and activated sludge and chlorine contact and conditions solids thermally prior to vacuum filtration. The tannery contributes about 18% of the total flow, but 80% of the suspended solids and biological oxygen demand. Suspended solids and biological oxygen demand removals have consistently been above 90%. The final effluent phosphorus concentration has been under 1.0 milligrams per liter, representing removal rates over 80%. This successful control of phosphorus in the effluent has been achieved by adding waste pickle liquor to the primary settling tank. This waste pickle liquor is obtained from steel mills in Gary, Indiana. No flocculating aids are necessary. It is necessary to add much larger amounts of this

iron solution when the tannery wastes are limited or not present than when they are present in considerable amounts. As a result, analyses are made on daily composite wastewater samples, and the iron feed is adjusted based on the previous day's operating results. (Carroll-FRC)

THE USE OF CONTAINER-REARED CULTURES OF CLADOCERA IN POLISHING FISH FARM EFFLUENTS,
Vsesoyuznyi Nauchno-Issledovatelskii Inst. Prodovogo Rynogo Khoziaistva Rybnoe (USSR).
I. B. Bogatova, and Z. I. Yerofeyeva.
Hydrobiological Journal, Vol 16, No 5, p 56-61, 1980. 1 Fig, 5 Tab, 12 Ref.

Descriptors: *Zooplankton, *Biofilters, *Fish farming, Daphnia, Cladocerans, Wastewater treatment, Invertebrates, Biological treatment, Organic matter, Settling tanks.

Mesh containers of cladocerans were immersed in fish farm waste settling tanks to remove excess organic matter before discharging the effluent into receiving waters. Daphnia magna, Moina macrocopa, Ceriodaphnia reticulata, and D. magna plus C. reticulata were used in 5 to 11 containers per pond, arranged in checkerboard fashion or longitudinally. Best results were obtained with Daphnia magna in 10 containers arranged in checkerboard order. Settling tanks with zooplankton had lower levels (19.1-24.5%) of organic matter in the sediment than the control (27.5%). Total nitrogen content and total phosphorus content were lower in tanks with cladocerans. Ammonia-N was increased. Adding the cladocerans to the tanks without enclosing them in containers was unsuccessful because fish escaped from the farm ponds into the settling tanks and ate large quantities of cladocerans. BACTERICIDAL AGENTS IN WASTEWATER LAGOONS AND LAGOON DESIGN,
Idaho Div. of Environment, Pocatello.
J. R. Moeller, and J. Calkins.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2442-2451, October, 1980. 5 Fig, 4 Tab, 27 Ref.

Descriptors: *Coliforms, *Ultraviolet radiation, *Design criteria, Bacteria, *Wastewater lagoons, Wastewater treatment, Lagoons, Chlorination, Disinfection, Irradiation, Hydrogen ion concentration, Activated sludge process, West Hickman Creek Wastewater Treatment Facility, *Kentucky.

A study was conducted at the West Hickman Creek Wastewater Treatment Facility, located on the Jessamine County-Fayette County line in Kentucky on West Hickman Creek. Treatment at this plant includes the Kraus modification of the activated sludge process, secondary treatment, four tertiary lagoons, and disinfection by chlorination just prior to discharge. The study was designed to determine more clearly the role of solar ultraviolet radiation in the destruction of coliform bacteria. Coliform concentrations were measured in each of the four lagoons. A close correlation between pH and coliform reduction was noted in earlier studies, but since the pH in the West Hickman lagoon system rarely exceeded 8.5, it is doubtful that this was a factor in coliform survival at this facility. Nutrient loading in terms of ortho-phosphorus, total phosphorus, and total Kjeldahl nitrogen remained essentially constant for the duration of the study, although total Kjeldahl nitrogen concentrations became erratic and increased by about 50% during the last 2 months of the study. Coliform densities were generally higher during winter than in summer. Declining doses of ultraviolet light in autumn may have partially contributed to the increase. It is also likely that the increase resulted from cessation of lagoon chlorination prior to initiation of the study. The data do, however, suggest the importance of ultraviolet light lethality to coliforms. A large and highly significant portion of the survival variance was correlated with ultraviolet dosage. Samples taken from low temperature waters exhibited greater destruction than can be reasonably explained by UV-B effects alone. (Baker-FRC)

RAPID-INFILTRATION RESEARCH AT FLUSHING MEADOWS PROJECT, ARIZONA,
Science and Education Administration, Phoenix, AZ. Water Conservation Lab.
H. Bouwer, R. C. Rice, J. C. Lance, and R. G. Gilbert.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2457-2470, October, 1980. 4 Fig, 3 Tab, 23 Ref.

Descriptors: *Infiltration, *Wastewater treatment, Secondary wastewater treatment, Effluents, Water quality, Basins, *Flushing Meadows Project, *Arizona, Water reuse, Conservation, Water conservation, Nitrogen, Phosphorus, Phosphates, Nutrients, Acidity, Groundwater recharge.

During the first five years of the Flushing Meadows Project, the main objective was to maximize hydraulic loading and to determine the associated quality improvement of the effluent as it seeped down to the groundwater and moved laterally through the aquifer. During the second five years the research comprised studying maximization of nitrogen removal, which required a reduction in hydraulic loading. The Project consisted of six parallel, horizontal basins. Secondary wastewater effluent from an activated sludge process with no chlorination was pumped into the basins at one end. The 5-day BOD generally was in the 10 to 20 mg/l range for secondary effluent going into the infiltration basins, and less than 1 mg/liter for the renovated water from the East Center Well. Chemical oxygen demand of the secondary effluent was 30-60 mg/l, and that of the renovated water, 10-20 mg/l. Total nitrogen content of the secondary effluent normally ranged between 20 and 40 mg/l, with the low values occurring in the summer. Phosphorus in the secondary effluent was mostly in the orthophosphate form. Concentrations of phosphate-phosphorus showed a slightly decreasing trend in the 10 years of the research, from an average of about 11 mg/l in 1969 to about 8 mg/l in 1977. This decrease can probably be attributed to an increase in household use of low phosphate detergents. The fluoride concentration of the secondary effluent decreased during 1973-77 and averaged 20.8 mg/l in 1977. Boron concentrations averaged 0.45 mg/l in 1968 and increased to 0.85 mg/l in 1971, decreasing to 0.59 mg/l in 1977. The secondary effluent contained 21 PFU's/l; viruses could not be detected in renovated water sampled below the basins. (Baker-FRC)

VELOCITY DEPENDENCE OF PHOSPHORUS TRANSPORT IN A PACKED-BED REACTOR,
Florida Univ., Gainesville. Dept. of Agricultural Engineering.
A. R. Overman, B. R. McMahon, and R.-L. Chu.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2371-2376, October, 1980. 9 Fig, 4 Ref.

Descriptors: *Model studies, *Phosphorus, *Packed beds, Wastewater treatment, *Velocity, Phosphorus transport, Mathematical equations, Mathematical studies, *Packed-bed reactor, Phosphorus kinetics.

A model is presented that provides a quantitative correlation between phosphorus kinetics and velocity in a packed-bed reactor. The model includes the processes of dispersion, convection, adsorption, transformation, decomposition, and reaction. Dispersion was found to be negligible compared with other processes. Decomposition and reaction were both shown to be velocity dependent, and accounted for the shift of the midpoint with velocity and the dependence of the overall reaction, respectively. The net rate of formation of fixed phosphate showed a strong dependence on velocity, which established the strong coupling between the hydrodynamic and chemical processes. (Baker-FRC)

WASTEWATER FROM A SUGAR REFINING INDUSTRY,
Mosul Univ. (Iraq).
S. Ahmad, and T. A. Mahmoud.
Water Research, Vol 16, No 3, p 345-355, March, 1982. 11 Fig, 4 Tab, 21 Ref.

Descriptors: *Wastewater treatment, *Sugar crops, Beets, Sugarcane, Chemical oxygen demand, *Iraq, Chemical analysis, Water analysis, Water quality.

Wastewater was collected from a sugar factory in Mosul which refines raw sugar for most of the year, except for a maximum of 40 days when it processes beet sugar, depending on the availability. The factory has a production capacity of 2000 t/day of beet sugar, 600 t/day of white sugar and 300 t/year of bakery yeast. It also produces 24,000 tons of lime. The quantity of wastewater produced per ton of sugar refined is relatively high, perhaps due to the fact that the quantity of water available and its cost are not yet limiting factors. There was considerable variation in the characteristics of the wastewater. The possible variations should be considered when designing any treatment facility. The kinetic coefficients determined by inexpensive batch reactor studies could be helpful in obtaining estimates of design data. The mathematical model suggested by Eckenfelder is applicable to sugar refinery wastewater. The Tucek model is applicable to data based on chemical oxygen demand values. The performance relationship as suggested by Tucek can be used to predict the efficiency of chemical oxygen demand for a given set of conditions. (Baker-FRC)

ORGANIC POLLUTANTS ADSORPTION FROM MULTICOMPONENT SYSTEMS MODELED BY FREUNDLICH TYPE ISOTHERM,
Technion-Israel Inst. of Tech., Haifa. Div. of Environmental and Water Resources Engineering.
C. Sheindorf, M. Rebhun, and M. Sheintuch.
Water Research, Vol 16, No 3, p 357-362, March, 1982. 10 Fig, 1 Tab, 3 Ref.

Descriptors: *Isotherms, *Mathematical equations, Temperature gradient, Thermocline, Langmuir isotherm, Freundlich isotherm, *Adsorption, Uptake, *Wastewater treatment.

A novel Freundlich-type multicomponent adsorption isotherm has been used to describe adsorption data in multicomponent systems. This isotherm is suitable for multicomponent systems that consist of components which obey a Langmuir isotherm when present as a single component. The isotherm was used to describe the adsorption of parabromophenol, phenol and benzensulfonate on activated carbon from the respective bicomponent and three-component aqueous solutions. This method demonstrated superiority over the commonly employed miltisection Langmuir isotherm. (Baker-FRC)

PH INFLUENCE ON ACIDOGENIC DISSIMILATION OF GLUCOSE IN AN ANAEROBIC DIGESTOR,
Amsterdam Univ. (Netherlands). Lab. of Chemical Technology.
R. J. Zoetemeyer, J. C. Van Den Heuvel, and A. Cohen.
Water Research, Vol 16, No 3, p 303-311, March, 1982. 7 Fig, 9 Tab, 18 Ref.

Descriptors: *Anaerobic digestion, *Acidity, *Wastewater treatment, Biodegradation, Bacteria, Anaerobic bacteria, Digestion, Activated sludge process, *Hydrogen ion concentration, Glucose.

The influence of the pH value on acidogenesis was investigated with reference to maximum specific growth rates and product distributions at various delution rates in order to optimize product distribution with respect to the more sensitive methanogenic stage. Glucose was used as the carbon limiting substrate, since its acidogenesis was rate limiting in the continuous flow stirred tank reactor (CFSTR). The gas phase consisted of carbon dioxide and hydrogen. Recovery of dissolved products,

LIBRARY U. OF I., URBANA-CHAMPAIGN

mainly short-chain fatty acids, gas and biomass, calculated as total carbon, amounted to 85-95%. Yield values ranged from 12 to 14%. An optimal growth rate of 0.33/hr was achieved at a pH of 6.0. Product distrubution at 90% of the maxiumum growth rate was fairly constant up to the pH value of 6.0, after which dramatic changes in the main product were found to occur, from butyric acid to lactic acid and subsequently to acetic acid, formic acid and ethanol. INDUSTRIAL WASTEWATER TREATMENT TECHNOLOGY--RECENT DEVELOPMENTS,
Vanderbilt Univ., Nashville, TN.
W. W. Eckenfelder, Jr.
Water Science and Technology, Vol 14, No 1/2, p 111-119, 1982. 5 Fig, 2 Tab, 3 Ref.

Descriptors: *Industrial wastewater, *Organic compounds, *Activated carbon, *Wastewater treatment, Technology, Activated sludge process, *Heavy metals, Adsorption, PACT process, Oxidation, Nitrification, Dentrification, Economic aspects, Costs.

Conventional treatment of industrial wastewaters is concerned with removal of BOD, suspended solids and certin specified pollutants: nitrogen, phosphorus, heavy metals, cyanide, and phenol. Recent legislation will require control of toxic organics and color in addition to the above pollutants. Emphasis is presently directed toward in-plant control technology or modifications of conventional technology. Some examples of source control are: precipitation of heavy metals followed by filtration or ion exchange if necessary, organics removal by oxidation using ozone or hydrogen peroxide with or without ultraviolet light or catalysts, adsorption on granular activated carbon or macroreticular resins, and air or steam stripping of volatile pollutants. In DuPont's PACT process powdered activated carbon is added to the activated sludge process. This results in improved removal of non-biodegradable organics and priority pollutants, especially under shock loads, dampening of effluent variability, improved hydraulic capacity, and enhanced nitrification. The performance characteristics of the PACT process are listed for several types of municipal and industrial wastewaters. PACT dosages ranged from 125-310 mg per liter. Economics of several treatment systems are compared for plants of 1, 10, and 50 mgd capacity. Lowest costs were activated sludge with solids handling and rotating biological contactors with solids handling; intermediate were activated sludge with 2-stage nitrification and solids handling and PACT with and without nitrification plus solids handling, regeneration, and carbon makeup; highest was physical chemical treatment with granular activated carbon. WASTEWATER TECHNOLOGIES IN SOUTH AFRICA: RESEARCH AND APPLICATION,
Water Research Commission, Pretoria (South Africa).
G. J. Stander, G. G. Cillie, E. J. Hall, and M. R. Henzen.
Water Science and Technology, Vol 14, No 1/2, p 465-480, 1982. 8 Fig, 1 Tab, 27 Ref.

Descriptors: *Research priorities, *Water reclamation, *Advanced wastewater treatment, Technology, Wastewater treatment, Industrial wastewater, Water reuse, Reverse osmosis, *South Africa, Public health, Water quality, Nutrient removal, Textile mill wastes, Pulp and paper industry, Ponds, Algae, Ultrafiltration, Ion exchange, Color removal, Dyes, Bardenpho process, Phosphorus removal, Phoredox process, Sludge treatment, Monitoring, Pollutant identification, Viruses, Carcinogens, Potable water.

Highlights of recent research and applications in South Africa cover water and wastewater management and water reuse. Potable water is produced at Windhoek, Namibia, by treating maturation pond effluent with high lime clarification, foam fractionation, clarification, breakpoint chlorination, activated carbon adsorption, and free residual chlorination. Quality control includes monitoring of volatile halogenated hydrocarbons and epidemiological studies. Municipal water reclamation plants are operated at Pretoria and Cape Town. Water reuse plants at two paper mills produce good guality effluents. Reverse osmosis, effective in removing accumulated inorganic salts, is currently under investigation. The Bardenpho process was a result of studies to remove nutrients without chemical addition. It consists of four stages--primary anoxic, primary aerated, secondary anoxic, and secondary aerated--followed by clarification. Organic matter in the wastewater is the sole carbon source. The Phoredox process is a refinement of the Bardenpho process. About 30 plants using these processes are presently operating in South Africa. Research on handling of the dilute sludge has tried dissolved air flotation, belt filters, centrifuges, polyelectrolytes, and land application. Nitrogen removal from an industrial effluent is being studied in a system of algae ponds with decreasng depth. (Cassar-FRC)

CRITERIA FOR NITRIFICATION IN FIXED FILM REACTORS,
Technical Univ. of Denmark, Copenhagen. Dept. of Sanitary Engineering.
P. Harremoes.
Water Science and Technology, Vol 14, No 1/2, p 167-187, 1982. 8 Fig, 3 Tab, 16 Ref.

Descriptors: *Nitrification, *Oxygen, *Ammonia, *Wastewater treatment, Biological treatment, Model studies, Organic matter, Dissolved oxygen, Trickling filters, Contact filters, Aerobic conditions.

A hypothesis concerning nitrification in fixed films, analytically modeled under simplified assumptions, agreed qualitatively with data from the literature. The postulation was that nitrification in fixed films can be achieved only when nitrifying bacteria embedded in a biofilm surface of mineralizing bacteria have sufficient exposure to aerobic conditions to multiply and reach concentrations high enough to convert ammonia. Several cases are considered: (1) the entire thickness of the biofilm is aerobic, (2) ammonia cannot fully penetrate the biofilm, (3) oxygen cannot fully penetrate the biofilm, (4) oxygen and ammonia fully penetrate the biofilm, and (5) the penetration of oxygen is greater than the penetration of ammonia. Oxygen penetrates deeper into the biofilm than soluble organic matter. In practice the soluble BOD should be limited to 20 mg per liter for 3 mg per liter dissolved oxygen. (Cassar-FRC)

HIGH-RATE ALGAE PONDS FOR WASTEWATER TREATMENT AND PROTEIN PRODUCTION,
Technion-Israel Inst. of Tech., Haifa. Dept. of Civil Engineering.
G. Shelef.
Water Science and Technology, Vol 14, No 1/2, p 439-452, 1982. 3 Fig, 2 Tab, 31 Ref.

Descriptors: *Algae harvesting, *Wastewater lagoons, *Feeds, *Wastewater treatment, Biomass, Algae growth, Photosynthesis, Nutrient removal, Bacteria, Proteins, Ponds, Lagoons, Productivity, *Israel.

Work on municipal wastewater treatment in high rate algae ponds (HRAP) began in Israel in 1968. This paper summarizes results of the 1975-80 period. Total biomass yields of 35-50 g per sq m per day or over 180 metric tons (dry) of mixed biomass per ha per year may be obtained with these systems. Bacterial productivity is fairly constant at about 20 g per sq m per day throughout the year. Algal productivity ranges from 10 g per sq m per day in winter to over 30 g per sq m per day in summer. The system is composed of a photosynthetic mixed meandering channel type pond 20-60 cm deep. Mixing is provided by paddle wheels or cage aerators to produce a longitudinal velocity of 5-10 cm per sec. The algal harvesting and processing units thicken, dewater, and dry the biomass for use as animal feed. Effluent is polished in an intermittent shallow coarse sand filter and chlorinator. Complete data are given for 12 months operation of a pilot pond using raw municipal wastewater from Haifa, Israel. This 120 sq m pond produced 1935 kg biomass (dry) in the 12 months starting September 1978. Effluent under favorable conditions averaged < 10 mg per liter total suspended solids, < 10 mg per liter total BOD, 50 mg per liter total COD, 24 mg per liter total N, < 0.5 mg per liter total P, and 100 per 100 ml total coliforms. Since no fertilizers, carbon source, pond liners, or axenic cultures are needed, production costs for the algal biomass are only $80 per ton sundried or $120 per ton drum dried after costs of secondary wastewater treatment have been deducted. DESIGN AND OPERATION INTERACTION--AN EXAMPLE: MAIN TREATMENT PLANT VIENNA,
Technische Univ., Vienna (Austria).
W. von der Emde.
Water Science and Technology, Vol 14, No 1/2, p 493-506, 1982. 3 Fig, 9 Tab, 10 Ref.

Descriptors: *Activated sludge process, *Sludge disposal, *Municipal wastewater, *Wastewater treatment, Incineration, Pilot plants, Biological wastewater treatment, Design criteria, Aeration, *Vienna, Austria.

The Main Treatment plant in Vienna, Austria, uses the high-rate activated sludge process (1.2 days sludge age and 1.5 hour hydraulic detention time). To minimize construction and operating costs four large aeration tanks of 10,000 cu m capacity each were installed. A plug flow mixing regime was specified. Aeration motors are direct-current so that speed may be easily decreased during periods of low oxygen demand. Sludge is incinerated with spent oil and garbage after dewatering and drying. Average wastewater flow in March 1981 was 656,400 cu m per day; influent COD, 756 mg per liter; influent BOD5, 323 mg per liter; effluent COD, 90 mg per liter; and effluent BOD5, 31 mg per liter. Overall removal efficiencies were COD, 88%; and BOD5, 90%. Details are given of the 16-year design, pilot plant, and full-scale studies that preceded the plant startup in October 1980. (Cassar-FRC)

Descriptors: *Industrial wastewater, *Wastewater treatment, *Flow pattern, Anaerobic digestion, Food-processing wastes, Wastewater facilities, Design criteria, Pilot plants, Prototypes, Beets, *Beet sugar industry.

The fluid flow pattern of a 30 cubic meter upflow reactor used for the anaerobic treatment of wastewater from a beet sugar factory was studied. The prototype 200 cubic meter reactor was constructed based on the results of experiments with the pilot reactor. Residence time distribution experiments were conducted in the prototype reactor using continuous injection of a lithium chloride (LiCl) solution as a tracer in the influent of the reactor and measuring the response to this stimulus at several locations in the reactor and in the effluent. These measured data were used to develop models of the fluid flow pattern which consisted of regions of ideal mixing, plug flow, dead space, and short circuiting. Comparisons of the fluid flow patterns of the pilot plant and the prototype indicated that three-mixer models were appropriate for the pilot plant, while two-mixer models were found for the prototype. The studies found that, at the influent concentrations and liquid residence times applied, the gas produced by the anaerobic bacteria provided good mixing of the fluid inside

the reactor. However, the settler on top of the reactor must be effectively shielded from the region in the reactor where the anaerobic conversion takes place. Dead space regions may be created by high concentrations of mud in the blanket, which cause extra thickening of the suspended solids in the bed. Experiments with the prototype reactor showed that upflow reactors for anaerobic treatment of wastewater should contain enough sludge to provide a sludge bed height of between 1.5 and 2.5 meters. Most of the influent bypassed the sludge bed at bed heights of 0.4 meters. (Carroll-FRC)

CARBON LIMITATION OF BIOMASS PRODUCTION IN HIGH-RATE OXIDATION PONDS,
Technion-Israel Inst. of Tech., Haifa. Environmental and Water Resources Engineering.
Y. Azov, G. Shelef, and R. Moraine.
Biotechnology and Bioengineering, Vol 24, No 3, p 579-594, March, 1982. 7 Fig, 5 Tab, 16 Ref.

Descriptors: *Photosynthesis, *Algal growth, *Carbon dioxide, *Oxidation ponds, Ponds, Wastewater ponds, Growth rates, Organic loading, *Wastewater treatment, Biomass, High rate oxidation ponds, *Israel.

Carbon was the limiting factor in biomass production in high rate wastewater oxidation ponds. This conclusion was reached by theoretical considerations and by field experiments performed near Haifa, Israel. The main contributor to algal photosynthesis was the dissolved carbon dioxide provided by bacterial degradation of the organic compounds in the wastewater. Atmospheric carbon dioxide was a minor contributor under conditions of high organic loading but was significant at low organic loadings. Adding carbondioxide gas to a pond during a period of high organic matter concentrations did not increase photosynthesis. Shallower ponds became carbon limited more quickly than deeper ponds. Addition of bicarbonate did not increase algal growth as did carbon dioxide. (Cassar-FRC)

KINETICS OF BIOFILM NITRIFICATION,
Eidgenoessesche Technische Hochschule, Zurich (Switzerland). Technisch-Chemisches Lab.
H. Tanaka, and I. J. Dunn.
Biotechnology and Bioengineering, Vol 24, No 3, p 669-689, March, 1982. 17 Fig, 11 Tab, 14 Ref.

Descriptors: *Nitrification, *Kinetics, *Biofilms, *Wastewater treatment, Oxidation, Ammonium, Nitrites, Oxygen, Chemical reactions, Model studies, Nitrosomonas, Nitrobacter.

Reaction rates of the two-step nitrification reaction (ammonia oxidation followed by nitrite oxidation) were studied in a fluidized sand bed biofilm reactor. Under low NH4+ concentrations, when the oxygen/NH4+ ratio in the bulk liquid was less than the stoichiometric coefficient (3.4 mg per mg), oxygen was rate limiting. Under low oxygen conditions the nitrite oxidation rate was lower than the NH4+ oxidation rate, leading to an accumulation of nitrite. pH had little effect on biofilm nitrification kinetics. Organic carbon oxidation in the biofilm reduced NH4+ and nitrite oxidation rates. The influence of oxygen penetration effects on the relative values of NH4+ and nitrite oxidation rates was caused either by the Nitrobacter location in the inner biofilm regions or by a saturation effect for oxygen. A differential diffusion-reaction model was used to simulate the experimental results. (Cassar-FRC)

WESTCHESTER COUNTY'S PEEKSKILL WASTEWATER TREATMENT PLANT REPLACES FIVE PLANTS,
W. G. Borghard, and W. B. Sinnott.
Clearwaters, Vol 11, No 4, p 11-14, December, 1981. 1 Fig, 2 Tab.

Descriptors: *Wastewater facilities, *Complete wastewater treatment, Water treatment facilities, Wastewater treatment, Wastewater management, Computers, Aeration lagoons, Activated sludge process, Sludge, Advanced wastewater treatment, *Westchester County, *New York.

After the energy crisis of 1973, a re-study of a proposed sludge disposal method was undertaken by the Westchester County Department of Environmental Facilities for the Peekskill Sanitary Sewer District. The study indicated that thickening, anaerobic digestion, utilization of methane gas, dewatering by centrifugation, and disposal through composting and/or landfill were the most economical processes; the original design was revised accordingly. New secondary treatment facilities utilize the activated sludge process with diffused air. The plant is designed for 10 MGD with provision for expansion to 15 MGD. Pretreatment of incoming flow causes it to pass through mechanically cleaned bar screens and then to grit chambers. Four primary settling tanks begin the primary treatment, and effluent from these tanks flows into secondary treatment by pipeline into aeration tanks. Mixed liquor flows to any of four final settling tanks. Chlorine is applied to the final effluent through a diffuser located immediately ahead of the plant effluent conduit. The final effluent discharges through diffusers in the ship channel of the Hudson River after passing through an outfall. Raw sludge is pumped from two combined sludge gravity thickeners by pumps to the primary digester. Dewatering is accomplished through the use of centrifuges. A UCS 3000 computer receives, records, totalizes, and prints all the analog data as well as the alarm status of over 110 items. Start-up of the sludge digestion process by filling the primary tank with a mixture of raw sludge and wastewater was not successful. The process was successfuly restarted with seed sludge trucked in from another Westchester County plant. (Baker-FRC)

CONVERSION OF AERATOR TO CHLORINE CONTACT TANK AT THE OWLS HEAD WATER POLLUTION CONTROL PLANT,
New York City Environmental Protection Administration.
J. J. Donnellon, and D. Katz.
Clearwaters, Vol 11, No 1, p 14-19, March, 1981. 6 Fig, 4 Tab, 4 Ref.

Descriptors: *Wastewater facilities, *Chlorination, Aeration, Disinfection, Design criteria, Water pollution control, Chlorine, *Owls Head Treatment Plant, *New York, *Water treatment.

A chlorination problem at the Owls Head Water Pollution Control Plant was solved by converting an idle aerator, which was situated adjacent to the plant effluent channel, to a chlorine contact tank. While the merit of this solution was immediately obvious, once suggested, in 1975, it was not recognized during long study and experimentation sessions, which were conducted from 1969 on. The major problem with the old chlorination system was a lack of sufficient contact time; it was decided to chlorinate in the final sedimentation tanks which would provide a detention of 68 minutes, as opposed to the previous 10 minute contact. The system of final tank disinfection, however, had several serious disadvantages. Although it did afford a long detention, it did not provide adequate mixing, and the chlorine demand was excessive due to the suspended solids in the final tanks. Thus it was necessary to dose at the rate that ranged from 80 to 100 gallons per M.G. The system was also dependent on stable final tank operation, and several of these failed during 1973. The two essential components in an efficient chlorination are contact time and mixing. The conversion the idle aerator at Owls Head provides an excellent example of the potential for improvement that may reside in existing plant facilities. (Baker-FRC)

USE OF SYNTHETIC ADSORBENTS IN CHEMICAL PROCESSES,
Rohm and Haas Ltd., Croydon (England).
R. M. Carlyle.
Effluent and Water Treatment Journal, Vol 22, No 2, p 55-59, February, 1982. 7 Fig, 4 Tab.

Descriptors: *Polymers, *Adsorbents, *Absorption, *Advanced wastewater treatment, *Organic compounds, *Tertiary wastewater treatment, Separation techniques, Wastewater treatment, Activated carbon, Pesticides, Organic solvents, Organic pesticides, Industrial wastes, Water treatment.

Some applications and properties of synthetic polymeric adsorbents are reviewed with special focus on the use of Amberlite synthetic adsorbents for the removal of organic compounds during water and wastewater treatment. The Ambersorb adsorbents have properties similar to those of activated carbon. The concentration of adsorbate solution, solution pH, and regeneration during the adsorption process influence the efficiency of absorption. Chemical regeneration, polar solvents regeneration, and stream regeneration are described. Phenol can be recovered from the effluents of bisphenol-A production by a solvent regeneration process which yields a production effluent with < 10,000 ppm of phenol and non-polar solvents. Phenol may also be recovered from cumene by the cumene process and from phenol-formaldehyde resin using a Grignard reaction. Similar methods are used for the recovery of pesticides of the substituted phenol or phenoxy acid type from their production wastewaters. When using synthetic adsorbents for the removal of ethylene dichloride from the production effluents of vinyl chloride and the removal of benzene, toluene and xylene from refinery effluents, steam regeneration processes yield an effluent of high quality. UPRATING SLUDGE DIGESTERS BY IMPROVING THE HEAT TRANSFER OF HEATAMIX UNITS,
Severn-Trent Water Authority (England).
J. Upton, and R. Schofield.
Effluent and Water Treatment Journal, Vol 21, No 12, p 538-540, December, 1981. 2 Fig.

Descriptors: *Sludge digestion, *Heat transfer, *Fouling, Heatamix units, *Leicester, *England, Anaerobic digestion, Digestion, Mixing, Sewage gas, Energy conservation, Performance evaluation, Flow pattern, Alteration of flow, Direct flow.

Poor performance in anaerobic sludge digestion tanks at the City of Leicester's Wanlip works was attributed to fouling of the heat exchange surfaces and inadequate design of the Heatamix units, which heat and mix the sludge. The units were operating with a heat transfer coefficient of 694 KJ per sq m per degree C per hour, 70% of the design figure. Since it was impractical in this case to change the gas flow rate, water flow rate, or water temperature, the Heatamix units were converted to a co-current flow arrangement. The pipe system was reversed so that the conventional water flow was reversed, hot inlet water was pumped to the bottom, and cooler water left from the top. Modification of the units increased the heat transfer coefficient to 1000 KJ per sq m per degree C per hour. (Cassar-FRC)

DOES CONVENTIONAL SEWAGE TREATMENT MEET THE DEMANDS OF THE 1980'S,
K. Stendahl.
Effluent and Water Treatment Journal, Vol 22, No 2, p 61-65, February, 1982. 6 Fig, 3 Tab, 6 Ref.

Descriptors: *Biological wastewater treatment, *Chemical precipitation, *Cost analysis, *Advanced wastewater treatment, *Phosphorus removal, Wastewater treatment, Chemical treatment, Phosphorus, Separation techniques, Physicochemical treatment, Filtration, Tertiary wastewater treatment, Evaluation, Standards.

The design and construction of sewage treatment facilities often follow conventional patterns based on increased demands and economic feasibility. Primary treatment mechanically removes coarse pollutants by screening and sedimentation. Secondary biological treatment breaks down organic pollutants. Phosphorus elimination is achieved by chemical precipitation during tertiary treatment. A fourth stage, filtration, may also be used for sensi-

LIBRARY U. OF I., URBANA-CHAMPAIGN

tive receiving waters. Chemical precipitation is also useful in removing biochemical oxygen demand, heavy metals, and other contaminants in wastewater. Experience in Sweden shows that biological treatment is better than chemical precipitation for the removal of BOD. A cost breakdown for the four treatment stages for various plant sizes based on the 1979 cost level in Sweden is given. Costs can be reduced if the biological stage is replaced by chemical precipitation in a two stage process, and if mechanical and chemical precipitation are combined in a single process. An English study estimated the energy cost to be 1.3 dollars-person/yr for biological treatment or 0.1 dollars-person/yr for chemcial treatment. A two stage plant which combines mechanical and chemical treatment can reduce the energy costs in the biological stage by about 33%. In the 1970s many plants in Norway introduced chemical precipitation processes to reduce phosphorus discharge to Lake Mjosa. A new sewage treatment plant planned for Oslo will be based on primary precipitation. (Geiger-FRC)

PHOSPHORUS REDUCTION STUDIES,
A. V. Gray.
Effluent and Water Treatment Journal, Vol 22, No 2, p 68-71, 73, 74, February, 1982. 5 Fig, 20 Ref.

Descriptors: *Phosphorus removal, *Chemical precipitation, *Eutrophication, *Advanced wastewater treatment, Wastewater treatment, Phosphorus, Nutrients, Sulfates, Biological wastewater treatment, Lime, Tertiary wastewater treatment, Separation techniques, Activated sludge, *Lough Neagh, *Northern Ireland.

Phosphorus enrichment in Lough Neagh, Northern Ireland has been occurring since about 1900 with the advent of the water closet and use of artificial fertilizers. Various measures were tried to control eutrophication caused by massive blooms of Anabaena flos-aquae. Temporary measures to control algal growth included harvesting of weeds or introducing grazing organisms. More permanant measures of nutrient reduction include flow diversion or dilution and chemical precipitation which are often performed at discharge or manufacturing sources. Phosphorus entering sewage treatment works comes from household detergents, human excreta, and industrial sources. Influent sewage can contain phosphorus in many forms. Some phosphorus is removed during normal sewage treatment processes. The Bardenpho process can remove up to 85% of the phosphorus under strict operating conditions. Chemical precipitation of phosphorus combined with mechanical dosing provides efficient removal of phosphorus from wastewaters. Split-effluent lime processing is advocated for achieving phosphorus reduction by treatment of secondary effluent during biological filtration. Operation of a ferrous sulfate dosing plant should prove the economic value of this method of phosphorus reduction at activated sludge plants. Other wastewater treatment plants in the Lough Neagh catchment area are scheduled to be installed in the near future to reduce phosphorus loading to this lake. (Geiger-FRC)

RE-EXAMINING THE KINETICS OF THE BIOCHEMICAL OXIDATION OF SEWAGE,
T. Stones.
Effluent and Water Treatment Journal, Vol 22, No 2, p 75, February, 1982. 1 Tab, 7 Ref.

Descriptors: *Kinetics, *Oxidation, *Dissolved oxygen, *Biochemical oxygen demand, *Wastewater, Mathematical equations, Nitrification, Wastewater treatment, Biological wastewater treatment, Mathematical studies, Ammonia, Domestic wastes, Sewage.

The oxidation of sewage occurs spontaneously when it is diluted with clean aerated water. In this two stage process, the carbonaceous matter is first oxidized over a period of 15 to 20 days, and the second stage consists of the oxidation (nitrification) of original ammonia and that produced during the first stage. The kinetics of the carbonaceous stage follow a second order reaction whose rate depends on the biochemical oxygen demand (BOD) and the residual dissolved oxygen (DO) concentration. An equation was given for the kinetics of the first stage oxidation for a .01 dilution of settled domestic sewage at 20 degrees. By using a value of 6.00 milligrams/liter as the total BOD, the biochemical oxidation of sewage closely conforms to a second order reaction with a mean velocity coefficient of 0.039 for most of the first stage. These findings show that the decreasing rate of oxidation as the first stage proceeds is governed by the conjoint effect of consequential reductions in the residual dissolved oxygen level and the unsatisfied carbonaceous BOD. OPERATION AND PERFORMANCE OF A NEW ACTIVATED SLUDGE PROCESS: THE CONTACT STABILIZATION EXTENDED AERATION HYBRID,
Toronto Univ. (Ontario). Dept. of Civil Engineering.
B. H. Paepcke, and P. H. Jones.
Water Science and Technology, Vol 14, No 1/2, p 367-380, 1982. 10 Fig, 5 Tab, 8 Ref.

Descriptors: *Activated sludge process, *Contact stabilization, *Aeration, Biological wastewater treatment, Wastewater treatment, Municipal wastewater.

A hybrid activated sludge process combined the contact stabilization process and the conventional extended aeration process. Data obtained at a full-scale municpal wastewater treatment plant showed that the hybrid process had advantages of both components. Process stability was good because the sludge in the stabilization tank was not exposed to shock loads as in the conventional plant. The total aeration period was 6 hours vs. 24 hours for the conventional process. Large variations in hydraulic and organic loadings were handled without upset using a smaller, less expensive aeration tank volume. Effluent quality was consistently good. Only occasionally did BOD or suspended solids concentrations exceed 6 mg per liter. The food: microorganisms rations, 0.01-0.08 kg BOD per kg of volatile suspended solids per day, were in the low range characteristic of the extended aeration process. For a plant treating stronger wastewaters, longer detention times would be required. (Cassar-FRC)

LAND EXTENSIVE PROCESSES FOR WASTEWATER TREATMENT AND DISPOSAL--A PERSPECTIVE,
Water Science Lab., Melbourne (Australia).
C. D. Parker.
Water Science and Technology, Vol 14, No 1/2, p 393-406, 1982. 35 Ref.

Descriptors: *Wastewater irrigation, *Wastewater lagoons, *Land application, Irrigation, Lagoons, Ponds, Melbourne, Werribee, Australia, Wastewater composition, Water pollution effects, Soil properties, Agriculture, Water reuse, *Wastewater treatment, Pastures, Odor control, Heavy metals, Metals, Accumulation, Organic compounds, Pathogens, Public health, Groundwater pollution, Tertiary wastewater treatment, Fate of pollutants, *Wastewater disposal.

Land extensive wastewater treatment processes (ponds/lagoons and irrigation) have been used by the cities of Melbourne and Werribee, Australia, and in other countries. These experiences have led to conclusions helpful to planners of land extensive systems. Flat or slightly sloping ground is best for irrigation; ponds can tolerate up to 10-20% slope. Tight clay soil is best for pond sides and bottoms, although seepage always eventually stops due to sealing with sludge and algal matter. Very permeable soil spreads viable pathogens rapidly. Soils differ in ability to retain nutrients and heavy metals. There must be a compromise between the goals of maximum crop yield and maximum wastewater disposal. Irrigation methods must be adapted to the crop grown. The composition of the wastewater, whether domestic, industrial, or mixed, must be considered. Objectives of the land extensive systems may be complete treatment of raw waste, secondary or tertiary treatment, disposal of final effluent, or reuse of final effluent. Possible adverse effects of lagoon systems are unpleasant odor, groundwater contamination, and high concentrations of algae in the effluent. Irrigation schemes may cause accumulation of heavy metals and bioresistant organics in the soil, transmission of pathogens, sewage sickness on pasturelands, and groundwater pollution. Options are available to minimize the effects of the above problems. (Cassar-FRC)

AMMONIA AND TOTAL KJELDAHL NITROGEN REMOVAL IN AERATED LAGOONS,
Utah State Univ., Logan. College of Engineering.
A. Pano, and E. J. Middlebrooks.
Water Science and Technology, Vol 14, No 1/2, p 381-391, 1982. 6 Fig, 5 Tab, 6 Ref.

Descriptors: *Nitrogen removal, *Wastewater lagoons, *Temperature effects, *Kjeldahl procedure, Detention times, Ammonia, Wastewater treatment, Aerated lagoons, Lagoons, Hydraulic loading, Aeration, Performance evaluation, Seasonal variation, Nitrification, Comparison studies, Oklahoma, Wisconsin, Mississippi, Illinois, Pennsylvania.

Five aerated lagoons located in Oklahoma, Wisconsin, Mississippi, Illinois, and Pennsylvania were monitored for ammonia-N and total Kjeldahl nitrogen (TKN) removal. The lagoons differed in climatic conditions and in wastewater compositions. Mean annual ammonia-N and TKN removals were 49-94% and 50-87%, respectively, except for the Pennsylvania system, which had zero ammonia-N and TKN removal. The percentage removals of ammonia-N and TKN increased with decreases in hydraulic loading rates and increases in detention time. Removals in summer months were 10-20% higher than in winter. Differences in performance were observed between surface-aerated lagoons and lagoons with diffused-air aeration systems. Temperature differences, rather than type of equipment, were the likely causes of these differences. Less than 45 days hydraulic retention time or more than 0.055 cu m per sq m per day resulted in no ammonia-N or TKN removal. There was no relationship between dissolved oxygen concentration and percentage TKN and ammonia-N removals. (Cassar-FRC)

ELECTROCHEMICAL PROCESSES FOR WASTEWATER TREATMENT,
Naples Univ. (Italy). Dept. of Sanitary Engineering.
L. Mendia.
Water Science and Technology, Vol 14, No 1/2, p 331-344, 1982. 2 Fig, 5 Tab, 11 Ref.

Descriptors: *Electrochemistry, *Phosphate removal, *Tertiary wastewater treatment, *Wastewater treatment, Electrolysis, Seawater, Chlorination, Disinfection, Flocculation, Clarification, Electrodes, Magnesium hydroxide.

An electrochemical treatment of wastewater-seawater mixtures, especially useful in coastal communities, is described. After bar screening and grit removal the sewage is mixed with seawater at ratios of 1:3 or 1:4. The mixture passes through an electrolysis cell at retention times of 5-20 sec. The effluent is sent to a clari-flocculator basin where sedimentation of suspended solids and disinfection occurs during a 60-90 min retention period. Sludge from the process can be recirculated because of its high chlorine content and need not be digested. Chemicals used in treatment are generated from the electrolysis process. Hydrogen, chlorine, and hydroxyl ions are produced at the electrode and further react with each other and seawater constituents to form flocculant (magnesium hydroxide) and disinfectants hypochlorite). Advantages of the electrochemical treatment are no chemical costs, small plant size, recovery of metals if desired, and good phosphate removal. In this study the electrolytic cell was made of 6 contiguous perforated silicon-iron blocks (anode) and six contiguous per-

forated sheet irons (cathode). Operating parameters were: current density, 200 A; anodic current density, 1.33 A per sq dm; potential difference, 4V; energy consumption, 0.53 kWh per cu m; and feed flow, 2000 liters per hour. Suspended solids removal was 97%; BOD removal, 57% and phosphates removal, 86%. (Cassar-FRC)

CONTROL OF BULKING SLUDGE--PRACTICAL EXPERIENCES IN AUSTRIA,
Technische Univ., Vienna (Austria).
N. F. Matsche.
Water Science and Technology, Vol 14, No 1/2, p 311-320, 1982. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Sludge bulking, *Activated sludge process, *Wastewater treatment, Sludge volume index, *Austria, Filamentous organisms, Bacteria, Chlorination, Oxidation, Technology, Anaerobic conditions, Formaldehyde, Nutrients, Settling velocity, Organic loading, Flow patterns, Plug flow, Food-processing wastes, Ferrous sulfate, Polyelectrolytes.

In Austria experience with bulking sludge control has been successful with several methods: increase in specific weight of the floc, damage to the filamentous organisms, removing conditions favoring growth of filamentous organisms, and producing conditions adverse to growth of filamentous organisms. The specific weight of the floc may be increased by omitting the primary sedimentation step, reducing the concentration of polyelectrolytes so that soil particles are later incorporated onto the floc, or adding ferrous sulfate. Chlorination successfully inhibits filamentous organism growth. Formalin at 100 mg per liter is detrimental to both filamentous bacteria and nitrifying organisms but not to sludge bacteria. Factors which favor growth of filamentous organisms are septic conditions and nutrient deficiencies. These may be minimized by adequate flow velocities, frequent sludge removal, lower organic loads, and nutrient additions. Processes can be modified to produce conditions adverse to filamentous organism growth: use of intermittent feeding, increase in denitrification, division of the aeration tank into small compartments to cause plug flow conditions, and installation of a contact tank ahead of the aeration tank. EXPERIENCE FROM 10 YEARS ADVANCED WASTEWATER TREATMENT--TECHNOLOGY AND RESULTS,
Uppsala Univ. (Sweden). Dept. of Limnology.
C. Forsberg, B. Hawerman, and B. Hultman.
Water Science and Technoloy, Vol 14, No 1/2, p 121-133, 1982. 2 Fig, 4 Tab, 31 Ref.

Descriptors: *Advanced wastewater treatment, *Phosphorus removal, *Chemical precipitation, Wastewater treatment, *Sweden, Eutrophication, Lakes, Nitrogen removal, Lake restoration, Heavy metals, Alum, Iron compounds, Coagulation, Nitrification, Chemical treatment, Technology.

Sweden's Environmental Protection Act of 1969 precipitated intensive construction of municipal wastewater plants during the 1970's. About 74% of the urban population is served by wastewater treatment plants with a combined biochemical and chemical treatment. The effluent goals are 15 mg per liter BOD7 and 0.5 mg per liter phosphorus. In certain cases more stringent standards are imposed. About 70% of the plants meet the requirements. In 1977 post-precipitation was used at 554 plants, direct precipitation at 138, pre-precipitation at 17, and simultaneous precipitation at 35. Aluminum sulfate was used at 600 plants, iron salts at 92 plants, and lime or combinations at the remainder. In the post-precipitation method several procedures are used to improve P removal and lower costs of chemical additions: 2-stage precipitation, recirculation of post-precipitation sludge to the activated sludge aeration basins, or biological P removal. Most of the 22 lakes evaluated have responded to the advanced wastewater treatment with lowered concentrations of P and organic matter. Half of these had lower chlorophyll a values and 6, significant increases in transparency. Heavily polluted lakes will not show decreases in chlorophyll until P concentration is decreased to less than 0.1-0.2 g per cu m. Nitrogen increased in 10 lakes and decreased in 4 lakes. Improvement is easier to achieve in deep stratified waters than in shallow vegetated lakes. (Cassar-FRC)

SOME PERSPECTIVES IN THE MODELLING OF BIOLOGICAL TREATMENT OF WASTEWATERS,
Newcastle upon Tyne Univ. (England). Dept. of Civil Engineering.
A. James.
Water Science and Technology, Vol 14, No 1/2, p 227-240, 1982. 4 Fig, 44 Ref.

Descriptors: *Model studies, *Design criteria, *Research priorities, *Biological wastewater treatment, Computers, Activated sludge process, Trickling filters, Filters, Settleable solids, Sludge volume index, Optimization.

Modeling of biological wastewater treatment is reviewed, with emphasis on areas of dispute and needs for further research. Models of dispersed growth are extremely useful in understanding process fundamentals. However, more recent developments using a variable yield are improvements over the fixed yield models. Use of steady-state equations and evaluation of coefficients need to be improved. Fixed film reactor models have not reached the same stage of development as the dispersed growth models. Understanding of percolating filters lags behind high-rate filters. Processes involved are very complex and reactions are rate-limiting, except with very thin films. Settlement of flocculent suspensions does not lend itself to simple mathematical description. At present it is best to use models involving a sludge concentration factor which can be obtained from sludge volume index/sludge age relationship rather than a difficult-to-evaluate coefficient. Optimization models have reached a high degree of sophistication, and there is little point in further research in this field. Computers are often used in the process design stage which comprises 10-15% of the total required design time. There are many opportunities in extension of computer aid to structural design, preparation of bills of quantities, and preparation of design drawings. (Cassar-FRC)

THE EFFECTS OF TEMPERATURE ON THE BIOCHEMICAL REACTION RATES OF THE ACTIVATED SLUDGE PROCESS,
Virginia Polytechnic Inst. and State Univ., Blacksburg, Dept. of Civil Engineering.
C. W. Randall, L. D. Benefield, and D. Buth.
Water Science and Technology, Vol 14, No 1/2, p 413-430, 1982. 11 Fig, 2 Tab, 17 Ref.

Descriptors: *Activated sludge process, *Temperature effects, *Kinetics, Nitrification, *Wastewater treatment, Oxygen requirements, Chemical reactions, Arrhenius equation, Aerobic digestion, Biological wastewater treatment, Microorganisms.

The effects of temperature change on biochemical reactions that occur in the activated sludge process were analyzed using experimental results and data from the literature. Results support the postulate that microbial population dynamics play an important role in temperature effects on biochemical reaction rates of mixed populations. Organic substrate stabilization follows the Arrhenius relationship over the temperature span 5-40C. Other biochemical reactions (production of cellular material, maintenance energy requirements, aerobic digestion, autooxidation of cellular material, and nitrification) generally follow the Arrhenius relationship from 5-10C. The Arrhenius relationship was valid for total oxygen consumption rates over the range 13-22C. The energy oxygenutilization coefficient was completely independent of temperature over the range 15-31.5C. Heterotrophs successfully metabolize substrate at lower temperatures than nitrifiers, and nitrite formers metabolize efficiently at lower temperatures than nitrate formers. (Cassar-FRC)

NITROGEN CONTROL AT THREE RELATED PLANTS,
Greeley and Hansen, Chicago, IL.
T. E. Wilson, E. D. Lukasik, and M. D. R. Riddell.
Water/Engineering and Management, Vol 128, No 12, p 43-44, 46, 50, 51. December, 1981. 4 Fig, 3 Tab, 8 Ref.

Descriptors: *Wastewater treatment, *Activated sludge, *Denitrification, *Nitrogen, *Sludge, Aeration, Biochemical oxygen demand, Settling basins, Retention capacity, Suspended solids, Effluent standards, *Chicago area.

Three large wastewater treatment plants near Chicago which incorporate full-scale nitrogen control processes are compared. Each has been operating in a nitrogen control mode for three years, with essentially the same liquid stream process flow. All three have excess flow retention basins. Plants at Waukegan and Gurnee are flexible in that they employ MID-Step nitrification, whereas the Clavey Road Plant has the advantage of greater aeration times and detention times. Studies of effluent quality show that performance of the Waukegan plant was less optimal than that of the Clavey Road or Gurnee plants. At the Waukegan plant design flow was exceeded during four months, and recycle streams caused excessively high loadings of biochemical oxygen demand and suspended solids. (Titus-FRC)

ENERGY CONSERVATION AND ALTERNATIVE ENERGY SOURCES IN WASTEWATER TREATMENT,
Anderson-Nichols and Co., Inc., Concord, NH.
E. L. Rushbrook, Jr., and D. A. Wilke.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2477-2483, October, 1980. 3 Fig, 5 Tab, 7 Ref.

Descriptors: *Biological wastewater treatment, *Anaerobic digestion, *Wastewater treatment, *Energy, *Cost analysis, Project planning, Maintenance costs, Biological filters, Construction costs, Aerobic digestion, Solar energy, Design criteria, Wastewater facilities, Operating costs, Hillsborough, *New Hampshire.

With the passage of the Federal Water Pollution Control Act Amendments of 1972, significant changes were made in the requirements for water pollution control. These amendments coupled with increased pressure for energy conservation spurred the municipality of Hillsborough to investigate alternative treatment processes and energy sources for its wastewater facility. As a result of energy use studies, the use of rotating biological contactors with anaerobic digestion was chosen for innovative funding in November 1978. The project capital cost for the collection system and construction of the treatment plant was estimated at over $5.3 million in cost-effect analyses. In 1979, the town of Hillsborough voted to appropriate funds for the project, and the EPA declared the proposed alternative an innovative technology which was eligible for 85% funding. The Hillsborough project was placed on the 1981 Construction Grants Project List. (Geiger-FRC)

Descriptors: *Organic loading, *Chemical oxygen demand, Process control, *Bulking sludge, *Dissolved oxygen, *Wastewater treatment, Activated sludge, Aeration, Biological wastewater treatment, Sludge conditioning, Microorganisms.

It is often difficult to draw well-defined relationships among aeration basin dissolved oxygen, chemical oxygen demand removal rate, and sludge bulking in wastewater treatment processes. To clarify this situation, experiments were carried out in continous flow, completely mixed activated sludge laboratory units operating at steady state on a settled domestic wastewater. A consistent relationship was found between the COD removal rate and the aeration basin DO level of the completely mixed activated sludge process. The data allows the establishment of COD removal rate/aeration basin DO level combinations that will prevent the development of large populations of filamentous organisms as well as the occurrence of bulking. An activated sludge that has bulked because of low aeration basin DO can be adjusted by raising the aeration basin DO to a value that prevents filamentous outgrowth from the floc. Scanning electron micrographs of activated sludge show the action of filamentous microorganisms in the bulking process. (Geiger-FRC)

SAFETY CONSIDERATIONS IN HANDLING ACTIVATED CARBON,
Environmental Services, Inc., Cleveland, OH.
G. E. Strudgeon, B. J. Lewis, W. W. Albury, and R. C. Clinger.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2516-2522, October, 1980. 4 Ref.

Descriptors: *Wastewater treatment, *Activated carbon, *Safety, *Hazards, Accidents, Design criteria, Adsorbents, Dissolved oxygen, Wastewater facilities, Hydrogen sulfide.

Some of the hazards connected with the use of activated carbon for the treatment of wastewater are identified along with specific design and operational measures to minimize these hazards. Dust and dust explosions are a hazard in the carbon unloading area. Waste flows from activated carbon units that become low in dissolved oxygen may cuase hydrogen sulfide gases to be released by anaerobic organisms. Oxygen can also be adsorbed by wet carbon. Carbon may bridge and collapse, burying heavy objects or personnel. Activated carbon also tends to corrode equipment. Two case histories are presented in which low oxygen levels in the activated carbon solumns caused dangerous and even fatal accidents. A third case study showed that harmful off-gases could be released from a carbon regeneration furnace. It was suggested that the atmosphere inside of the vessel be checked, better ventilation installed, and probes be used to check carbon bridging to alleviate some of the hazards in an activated carbon facility. START-UP PROBLEMS OF SLUDGE DEWATERING FACILITY,
Los Angeles County Sanitation Districts, CA.
B. E. Hansen, W. E. Garrison, and D. L. Smith.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2558-2570, October, 1980. 12 Fig, 3 Tab, 3 Ref.

Descriptors: *Design criteria, *Dewatering, *Scaling, *Foaming, *Wastewater facilities, Sludge conditioning, Sludge thickening, Wastewater treatment, Sludge digestion, Chemical treatment, *Sludge drying.

Problems in the start-up of the Joint Water Pollution Control Plant of the County of Los Angeles are described. Substantial changes in the digested sludge characteristics from 1970 to 1978 resulted in a finer, more dilute sludge. Scaling and foaming were also a problem. To control the scaling problem, work on a sulfuric acid addition project to control the pH of the feed sludge was undertaken. Foaming was partially corrected by feeding the digested sludge directly to the basket centrifuges. Since particles of the digested sludge solids played an important part in the sludge dilution, a return to a 3% sludge feed concentration and coarser particle size distribution resulted in adequate performance. The automation of polymer feed rate and the use of chemical dewatering aids also helped to stabilize plant performance. (Geiger-FRC)

MECHANISMS AND METHODS FOR POLYMER CONDITIONING OF ACTIVATED SLUDGE,
Missouri Univ.-Columbia.
J. T. Novak, and B.-E. Haugan.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2571-2580, October, 1980. 13 Fig, 10 Ref.

Descriptors: *Activated sludge, *Flocculation, *Mixing, *Dewatering, *Polymers, Wastewater treatment, Sludge thickening, Sludge conditioning, Model studies, Filtration, *Sludge drying.

Studies were conducted to uncover the mechanisms by which cationic polymers improve the dewatering of activated sludge of wastewater treatment plants. The effects of polymer dosing and mixing on sludge dewatering and floc stability were evaluated by a proposed floc surface model. The amount of polymer required was found to be dependent upon the mixing speed, mixing time, and sludge solids concentration. Tests with a pilot filter press confirmed the model predictions for filter performance. The optimal dose of polymer needed for filter press operation can be estimated by using the European recommended 'standard stirring device' which provides a mixing speed of 1,000 revolutions/min. Polymer additions to the sludge should be conducted at an energy input level similar to that in the standard stirrer. Undermixing could result in a sludge cake with lowered solids content while wasting expensive synthetic polymers. (Geiger-FRC)

COMPARATIVE DISINFECTION BY BROMINE CHLORIDE AND CHLORINE OF VIRUSES AND BACTERIA IN WASTEWATER,
Baylor Coll. of Medicine, Houston, TX.
B. H. Keswick, R. S. Fujioka, P. C. Loh, and N. C. Burbank.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2581-2588, October, 1980. 5 Tab, 21 Ref.

Descriptors: *Disinfection, *Bromine, *Chlorine, *Coliforms, *Enteroviruses, *Wastewater treatment, Halogens, Residual chlorine, Chlorides, Bacteria, Enteric bacteria, Viruses.

The efficiency and feasibility of using BrCl in place of Cl in the disinfection of human enteric viruses and indicator bacteria usually present in wastewater effluent was evaluated under field operating conditions. BrCl or Cl solutions were automatically and simultaneously injected into model contact chambers with activated sludge effluent flowing through them at a rate of 15.1 l/min with a contact time of 15 to 30 min. BrCl was found to be a more effective disinfectant than Cl for several human enteric viruses as well as for some naturally occurring coliform indicator bacteria. Whereas Cl was more effective in disinfecting human enteric viruses than coliform bacteria, BrCl was found to be equally effective against both types of pathogens. BrCl required a shorter contact time for efficacy than Cl, but the resulting residual BrCl was unstable compared with the stable residuals formed by Cl. These findings indicate that BrCl is a better disinfectant than Cl for use in the treatment of wastewater. (Geiger-FRC)

SULPHIDE CONTROL IN RISING MAINS,
Severn-Trent Water Authority (England).
I. W. Griffiths.
Water Pollution Control, Vol 80, No 5, p 644-647, 1981. 1 Tab.

Descriptors: *Sulfides, *Water mains, Water transport, Septic wastewater, Sewers, Rural areas, Sodium compounds, Nitrogen compounds, Iron compounds, Cost analysis.

Three separate rural sewerage systems in the Upper Severn Division of the Severn-Trent Water Authority, Great Britain, experienced severe difficulties as a result of sulfide produced from septic sewages. Several chemical treatments designed to prevent the production of sulfide were investigated in the laboratory and at operational levels. Treatments investigated included hydrogen peroxide, sodium nitrate, ferric nitrate, and a solution of ferric sulfate spiked with a little nitric acid. A solution of ferric sulfate and nitric acid, with a strength equivalent to 42,000 milligrams per liter nitrate nitrogen and 125,000 milligrams per liter ferric iron, was found to be the most cost effective of the treatments evaluated for overcoming the septicity problems in sewer mains. Although attempts to correlate chemical dosing levels with flow, retention period, and sulfide concentrations in the sewers were unsuccessful, a consistent relationship was found between total internal surface area of the main and the dose rate required per hour of pumping. Since the size of the dosing pump is critical to efficient treatment, it is necessary to calculate the dosage level requirements on a particular main prior to treatment. The costs of treatment vary with respect to the length and diameter of the rising main and with the frequency and duration of pumping. (Carroll-FRC)

CHEMICAL AND BIOCHEMICAL OXYGEN DEMAND AS INDICATORS OF BIODEGRADABLE SUBSTRATE CONCENTRATION,
Technion - Israel Inst. of Tech., Haifa. Environmental Engineering Labs.
M. Green, G. Shelef, and R. Moraine.
Water Pollution Control, Vol 80, No 5, p 655-658, 1981. 1 Fig, 4 Tab, 10 Ref.

Descriptors: *Biological wastewater treatment, *Oxygen demand, *Substrates, Biodegradation, Chemical oxygen demand, Biological oxygen demand, Wastewater treatment.

The use of biological oxygen demand (BOD) as a measurement of organic substrate concentration in biological wastewater treatment processes was compared with the use of chemical oxygen demand (COD) for this purpose. This study also investigated the questions of whether BOD may underestimate substrate concentration and whether COD values may be used with certain modifications in kinetic models relating biomass growth rate to total substrate concentration. The 5-day biochemical oxygen demand test and the ultimate BOD test were both found to underestimate the true concentration of biodegradable substrate in wastewater and the incremental amount which is removed by biological activity. The COD test can be readily used to describe changes in the substrate concentration and to compute substrate removal rates and biomass yields. In order to use the COD test for kinetic models which involve the total substrate concentration rather than the incremental one, it is first necessary to overcome the problem caused by the nonbiodegradable fraction of the COD. This can be accomplished by estimating the nonbiodegradable fraction, which is fairly constant for a given type of sewage and under the typical range of activated sludge operating condtions. Laboratory experiments can contrive conditions which will result in a constant ratio of effluent COD to nonbiodegradable COD by maintaining the product of biomass concentration and residence time at a constant value. (Carroll-FRC)

A COMPARISON OF THE CARBONACEOUS OXYGEN DEMANDS OF A DOMESTIC AND INDUSTRIAL SEWAGE,
T. Stones.

Water Pollution Control, Vol 80, No 5, p 659-662, 1981. 3 Fig, 4 Tab, 8 Ref.

Descriptors: *Oxygen demand, *Wastewater oxidation, Biochemical oxygen demand, Chemical oxygen demand, Wastewater treatment, Wastewater analysis.

Sewage is characterized on the basis of its demand for oxygen. Since this demand is determined by the amount of oxidizable matter in the sewage,oxygen demand is designated as the sewage's strength. Arbitrary criteria which have been adopted as parameters for assessing the strength of sewage include the 5-day biochemical oxygen demand (BOD) and the permanganate value. However, these measures will provide truly comparative results only if the oxidation always occurs at the same rate, so that the measures always give the same constant proportion of the total carbonaceous oxygen demand. Experiments with industrial and domestic sewages showed that the proportions of the total carbonaceous oxygen demand represented by the 5-day BOD and by the permanganate value were not constant, but varied with the nature of the sewage. In addition, the two measures may give conflicting results. A low 5-day BOD may not necessarily represent a weak sewage, but rather one that contains a relatively high proportion of carbonaceous matter which is inert to biochemical oxidation. Similarly, a high permanganate value may not represent a strong sewage, but rather result from one that is rapidly oxidized by acid permanganate, giving an unrealistically inflated value for its strength. However, the ratio of the 5-day BOD of a sewage to its COD does provide a rational indication of its amenability to treatment. (Carroll-FRC)

THE PERFORMANCE OF AN OFF-SEWER STORM-SEWAGE TANK,
Secretary of State for Scotland, Edinburgh. Scottish Development Dept.
R. J. A. Henderson, W. McBain, and F. Pettigrew.
Water Pollution Control, Vol 80, No 5, p 582-599, 1981. 10 Fig, 6 Tab, 4 Ref.

Descriptors: *Combined sewer overflows, *Storage tanks, *Storm sewers, *Storm wastewater, Wastewater disposal, Wastewater management, Water pollution control, Performance evaluation.

In many areas, municipal sewage and storm water are discharged to a combined sewer system. When heavy rain results in system overloads, the normal practice is to relieve the drainage system through controlled spillages into a watercourse. The use of storage tanks to collect initial storm overflows, with further flow discharged over the tank outlet weir to the watercourse, is increasing. The Bannockburn sewer catchment in Scotland, which is served by both separate and combined drainage systems, uses an off-sewer storm-sewage tank overflow system for storm water management. The storm-sewage arrangement consists of a circular, 20 meter diameter storage tank with a peripheral overflow weir discharging to the Bannockburn watercourse. This paper describes research designed to quantify some of the benefits ascribed to the use of storage tanks at storm-sewage overflows. The pattern over time of the biochemical oxygen demand (BOD) and suspended solids concentration of the overflow sewage showed a high pollution intensity at the start of an overflow event, followed by a steady decrease in strength. Investigations showed that by the time the storage tank was filled, the strength of the inflow was well below the strength of the original inflow and also weaker than the partially-settled sewage being overflowed to the river. In this case, diversion of sewer overflow directly to the river when the tank was full provided the best management alternative. When limits on the concentration of the discharge are to be enforced, plotting of time against BOD and suspended solids concentrations will provide information on the point at which the strength of the overflow falls below the required limit. The storage tank must be large enough to collect the volume of overflow before this point. Several methods for determining this volume are discussed. (Carroll-FRC)

THE COLESHILL ADVANCED WASTE-WATER TREATMENT PLANT,
Water Research Centre, Marlow (England).
N. B. Banks, and A. J. Butwell.
Water Pollution Control, Vol 80, No 5, p 559-570, 1981. 9 Fig, 4 Tab, 9 Ref.

Descriptors: *Wastewater facilities, *Wastewater treatment, Physicochemical treatment, Pilot plants, Advanced wastewater treatment, England, Research facilities, Coleshill Experimental Plant.

The Coleshill Experimental Plant, formerly the Coleshill Advanced Waste-Water Treatment Plant, was built as a pilot plant for the investigation of the applicability of physicochemical methods of treatment to British sewages and as a proving ground for sewage-treatment projects generally. The plant and its antecedents are described. Experimental work conducted at the plant since partial operation began in 1975 has included study of chemically-aided sedimentation, including lime treatment, ferric sulfate, aluminum sulfate, phosphate removal, cost of chemicals, sludge production, and total costs; treatment in granular activated carbon columns, including downflow experiments and carbon capacity; and comparison of physicochemical treatment and activated sludge treatment. The pilot plant is now managed by the Water Research Centre. Several modifications are envisioned as part of this new role. New areas of research which will be addressed in the future are identified. A COMPUTER-BASED CENTRALIZED CONTROL AND SUPERVISORY SYSTEM FOR THE DAVYHULME SEWAGE TREATMENT WORKS,
Kennedy and Donkin (England).
M. R. Windle, and T. E. Chappell.
Water Pollution Control, Vol 80, No 5, p 663-673, 1981. 3 Fig.

Descriptors: *Wastewater facilities, *Computers, *Automation, Wastewater treatment, Design criteria, Monitoring, Process control, Remote control, Telemetry, Performance evaluation, Planning, Davyhulme.

The Davyhulme sewage treatment works in Great Britain treats the sewage and industrial effluent from the Greater Manchester metropolitan area. Since the original Davyhulme plant was completed in 1894, major extensions have been made periodically. The works now includes two activated sludge plants, with a third activated sludge plant planned for the future. The control and instrumentation equipment for the plants is generally mounted individually on the plant or grouped on control panels local to the plant and staffed by plant attendants on a permanent or roving basis. The interrelated operation of the existing plant with the new inlet facilities added during 1980 and the need for integrated operation of the old and new facilities, together with the considerable amount of control and instrumentation equipment associated with the new inlet works, focused attention on the need for centralized control and supervision of the plant. A review of the feasibility and cost-effectiveness of central control options indicated that the older activated sludge plant should be provided with centralized plant monitoring facilities, but that operation of the plant should be carried out by local plant operators under the control of the operator in the central control room, while the newer activated sludge plant should be provided with central remote control and supervision. An evaluation of three centralized control and supervisory systems concluded that a computer-based telemetry system was most appropriate in view of planned expansions. This system provides telemetry outstations for the transmission of control from and indication signals to a central master station and computer, direct digital control, software-based sequence control, centralized fire alarm annunciators and communications, and provisions for emergency operation. Specific design features and evaluation criteria are discussed. (Carroll-FRC)

PRODUCTION AND CONDITIONING OF SLUDGES FROM A HIGH-RATE BIOLOGICAL FILTER,
Commonwealth Scientific and Industrial Research Organization, Rockhampton (Australia). Meat Research Lab.
S. P. Moodie, and B. V. Kavanagh.
Water Pollution Control, Vol 80, No 5, p 674-681, 1981. 6 Fig, 3 Tab, 19 Ref.

Descriptors: *Biological filters, *Sludge conditioning, *Industrial wastewater, Food-processing wastes, Wastewater treatment, Clarification, Sedimentation, Chemical oxygen demand, Dewatering.

The treatment of meat processing wastewaters with pilot-scale biological filters has been the subject of several studies. However, most of these studies have investigated the effects of various operating variables on the removal of chemical oxygen demand (COD) from the wastewater. Little attention has been given to clarification of the effluent from these filters or to the disposal of the resulting sludges. This study of the use of pilot-scale high-rate biological filters for the treatment of meat processing wastewaters examined the settling characteristics of the effluent from the filter, the rate of sludge production, and the dewatering and chemical conditioning of the effluent from the filter. The emphasis of the study was on the development of information for design purposes. The study found that effluents from high-rate biological filters typically contain high levels of suspended solids and COD. As a result, clarification of these effluents is a significant factor in determining the overall degree of COD removal. Settling tests showed that meat processing wastewater requires a clarifier surface overflow rate of about 50 cubic meters per square meter per day to achieve removal of between 80 and 95% of settleable solids. The amount of sludge produced was found to be independent of the hydraulic rate and to have a mean value of about 0.35 kg dry solids per kilogram COD removed. Measurements of the specific resistance to filtration of the biological filter sludge indicated that chemical conditioning of the sludges would be necessary to facilitate dewatering by such devices as rotary vacuum filters or filter presses. Commercially available cationic polyelectrolytes and inorganic coagulants such as ferric chloride and alum were shown to be effective conditioning agents. (Carroll-FRC)

ORGANIC GROUPS AND MOLECULAR WEIGHT DISTRIBUTION IN TERTIARY EFFLUENTS AND RENOVATED WATERS,
Technion - Israel Inst. of Tech., Haifa. Environmental and Water Resources Engineering.
J. Manka, and M. Rebhun.
Water Research, Vol 16, No 4, p 399-403, April, 1982. 4 Fig, 3 Tab, 19 Ref.

Descriptors: *Pollutant identification, *Humic acids, *Tertiary wastewater treatment, *Advanced wastewater treatment, *Organic compounds, *Ultrafiltration, *Clarified wastewater, Separation techniques, Organic matter, Biological wastewater treatment, Chemical treatment, Clarification, Wastewater treatment, Lime, Chemical oxygen demand.

The molecular weight (MW) distribution and group composition of soluble organics in effluents from successive biological and chemical treatment stages were studied in efforts to follow their removal during advanced wastewater treatment processes. Molecular weight distributions were determined by ultrafiltration of effluent samples collected over a period of almost 2 years from the oxidation pond, lime clarifier, and after-lime polishing pond at the first-stage treatment plant of the Dan region Sewage Reclamation Plant at Tel-Aviv. The effluent contained relatively high COD and nitrogen levels. The effluents from the lime clarifier and after lime polishing pond were low in suspended solids and BOD and very low in phosphate. Humic substances were the most prevalent organic group in the oxidation pond samples, followed by proteins. The removal of 70% of the humic acid substances occurred in the lime clarifier. In the secondary effluents, about 61% of the

LIBRARY U. of I. URBANA-CHAMPAIGN

organics are included in the highest MW fraction. Maximum removals are obtained from the two highest MW fractions (72 and 65% respectively) in the advanced treatment. A correlation was noted between the emergence of an unidentifiable fraction after lime treatment and an increase in the lowest MW fraction in terms of absolute COD units. (Geiger-FRC)

SELECTED ORGANIC PESTICIDES, BEHAVIOR AND REMOVAL FROM DOMESTIC WASTEWATER BY CHEMICAL AND PHYSICAL PROCESSES,
North Texas State Univ., Denton. Inst. of Applied Sciences.
F. Y. Saleh, G. F. Lee, and H. W. Wolf.
Water Research, Vol 16, No 4, p 479-488, April, 1982. 2 Fig, 7 Tab, 13 Ref.

Descriptors: *Biological wastewater treatment, *Chemical coagulation, *Physicochemical treatment, *Organic pesticides, *Herbicides, *Halogenated pesticides, Domestic wastes, Wastewater treatment, Chemical treatment, Organic compounds, Separation techniques, Organic wastes, Pesticides, Activated carbon, Filtration.

The removal of selected chlorinated hydrocarbon pesticides and chlorophenoxy herbicides from a domestic wastewater by different regimes of biological, chemical, and physical treatment processes was examined qualitatively and quantitatively. Qualitative characteristic profiles showed a limited number of refractory organic residues on the chromatograms of extracts from each of the treatment units. In the biologically treated wastewater, 13 compounds including DDT and its metabolites, aldrin, dieldrin, and 2,4-D alkyl esters and salts were detected at the parts per trillion level. Chemical coagulation with alum-lime or lime-ferric chloride yielded slight reductions in the organic residues detected on the chromatograms. Mutimedia filtration had no noticeable effect on the organic residues remaining in wastewater after biological or chemical treatment. Activated carbon columns offered maximum removal of refractory organic residues when used for less than one year. The use of several sequences of treatment processes on domestic wastewater provided a high quality effluent virtually free of detectable organic residues. (Geiger-FRC)

INVESTIGATIONS OF NATURAL HUNGARIAN ZEOLITE FOR AMMONIA REMOVAL,
Veszpremi Vegyipari Egyetem (Hungary). Inst. for Analytical Chemistry.
J. Hlavay, G. Vigh, V. Olaszi, and J. Inczedy.
Water Research, Vol 16, No 4, p 417-420, April, 1982. 4 Fig, 2 Tab, 13 Ref.

Descriptors: *Separation techniques, *Ammonia, *Ion exchange, *Zeolites, *Nitrogen removal, Wastewater treatment, Municipal wastewater, Particle size, Cations, Synthetic hydrology, Nitrogen, Denitrification, Ammonium compounds.

Natural zeolites containing clinoptilolite have ion exchange properties showing a great affinity and selectivity for ammonium ions. The use of zeolite formed columns from Tokaj Mountain in Hungary for the removal of ammonia from synthetic and municipal wastewaters was studied under laboratory conditions. Particle size of the clinoptilolites played an important part in column performance. Na-from clinoptilolite in the particle size range of 0.5-1.0 mm gave optimal ion exchange at 5-7 BV/hr. Approximately 4.50 milligrams of ammonia-N/gram of clinoptilolite ammonia breakthrough capacity was achieved using synthetic wastewater in a column with inside diameter of 0.5 cm and 92 cm in length. Ten to twenty BV (bed volumes) of regenerant were required to remove 98-99% of the ammonia with flow rates of 5-7 BV/hr during regeneration of the ion exchange bed. (Geiger-FRC)

CONTROL OF ACTIVATED SLUDGE FILAMENTOUS BULKING--IV. EFFECT OF SLUDGE REGENERATION,
Prague Dept. of Water Technology and Environmental Engineering (Czechoslovakia).
J. Chudoba, M. Dohanyos, and P. Grau.
Water Science and Technology, Vol 14, No 1/2, p 73-93, 1982. 9 Fig, 1 Tab, 37 Ref.

Descriptors: *Sludge volume index, *Activated sludge process, *Regeneration, *Accumulation, Oxidation, Filamentous microorganisms, Microorganisms, Population dynamics, Wastewater treatment.

The accumulation-regeneration theory of microorganisms selection in activated sludge was verified in the laboratory. This theory is based on the observation that activated sludge organisms accululate and store soluble substrate prior to replication. This quantity of accumulated substrate is the accumulation capacity. It is assumed that the predominant microorganisms in a mixed culture are those with the highest accumulation capacity and rates. A sufficient regeneration period, which allows time for oxidation of the accumolated substrate, is necessary for optimum operation. An accululation-regeneration model is given. The two key parameters are the quantity of substrate removed which should be oxidized during the regeneration period and the average heterotrophic respiration rate in the whole system. The regeneration period is defined as the total period of activated sludge aeration in one accululation-regeneration cycle. Sludge volume index decreased with increases in the proportion of substrate oxidized and was < 200 ml per g only if more than 50% of the substrate was oxidized. Methods of reducing sludge bulking are illustrated in diagrams. (Cassar-FRC)

PROTEIN RECOVERY FROM DAIRY INDUSTRY WASTES WITH AEROBIC BIOFILTRATION,
Victoria Univ. of Manchester (England). Pollution Research Unit.
A. D. Wheatley, R. I. Mitra, and H. A. Hawkes.
Journal of Chemical Technology and Biotechnology, Vol 32, No 1, p 203-212, January, 1982. 4 Fig, 5 Tab, 14 Ref.

Descriptors: *Dairy industry, *Proteins, *Fungi, Wastewater treatment, Biofiltration, Filtration, Fusarium, Geotrichum, Aerobic conditions, Food-processing wastes.

The feasibility of recovering single cell protein on dairy industry wastes was studied. Field observations showed that wastes from five food or pharmaceutical plants (low pH and > 2.5 kg BOD loading per day) produced a predominantly fungal biomass. The most common species were Geotrichum and Fusarium. A detailed study of dairy wastes (butter, cream, milk bottling, cheese, yogurt, dried milk, and combinations of these) showed variations in species with type of waste and organic loading. In batch cultures Fusarium and Geotrichum grew within a pH range of 2-10, but the 5-8 range was optimal. Geotrichum grew between 7 and 35 C (optimum 28-31 C) and Fusarium grew between 12 and 36 C (optimum 28-30 C). Continuous cultures on horizontal fixed films produced 100 and 75 g per sq m of surface (dry weight) of Geotrichum and Fusarium, respectively. Biomass and growth rate were dependent on applied organic loading. A pilot plant for treating cheese, butter, and cream production wastes was run at pH 4-5 and 5-10 kg BOD per day per cu m. BOD removal was 30-50% and biomass production 0.1-0.5 kg per day (dry weight). The amino acid content was similar to that of other single cell proteins. The biomass was white and had a slight odor of stale milk. (Cassar-FRC)

INFLUENCE OF HIGH PARTIAL PRESSURE OF CARBON DIOXIDE AND/OR OXYGEN ON NITRIFICATION,
Water Research Center Stevenage (England).
G. L. Jones, and A. R. Paskins.
Journal of Chemical Technology and Biotechnology, Vol 32, No 1, p 213-223, January, 1982. 7 Fig, 3 Tab, 29 Ref.

Descriptors: *Nitrification, *Oxygen, *Carbon dioxide, *Bacteria, Wastewater treatment, Growth rates.

The high concentrations of carbon dioxide and oxygen in the mixed liquor of intensive wastewater treatment processes such as the oxygen activated sludge process. the Deep Shaft process, and the fluidized bed reactor inhibit nitrification. Mixed cultures of nitrifiers were exposed to different proportions of C02 and 0 while being maintained at constant pH (7.8) and temperature (20 C). The specific growth rate of the nitrifying bacteria was independent of C02 concentration to 20% produced acidic conditions. Addition of NaOH to maintain constant pH caused a buildup of Na ions to 26 g per cu dm after 10 days and a 50% reduction in dry weight of the culture. Nitrification was only 40-50% at pH 7.4 and nearly zero at pH 6.8 and below, compared with 100% at pH 7.8. Nitrifying bacteria were initially inhibited by high partial pressures of 0 but appeared to acclimatize and retain the ammonia-oxidizing ability even after exposure to lower partial pressures for several generations and subsequent reexposure to higher pressures. W82-05498

THE INFLUENCE OF NITROGEN ON PHOSPHORUS REMOVAL IN ACTIVATED SLUDGE PLANTS,
Meiring (P. G. J.) and Partners (South Africa).
J. L. Barnard.
Water Science and Technology, Vol 14, No 1/2, p 31-45, 1982. 10 Fig, 2 Tab, 23 Ref.

Descriptors: *Activated sludge process, *Nitrogen removal, *Phoshorus removal, Wastewater treatment, Nitrates, Nitrification, Denitrification, Anaerobic conditions, Phoredox process, Dissolved oxygen, Oxygen, Organic carbon, Sedimentation, Sludge.

Nitrates can interfere with phosphorus removal in activated sludge plants under some conditions. Nitrates serve as alternate sources of oxygen, preventing anaerobic conditions. Nitrification should be avoided and nitrate concentrations kept low. When nitrification is required, the nitrates must be reduced to low levels by internal denitrification. Sufficient carbon (ratios of COD: TKN of 10:1 or greater) for nitrate removal and anaerobic conditions in a specific zone of the plant ensures good phosphate removal. Several practical meaures may be considered to achieve N and P removal at lower COD:TKN ratios: (1) partial bypass of the primary sedimentation process, (2) sludge return at times of low load, (3) avoidance of aeration or turbulence in the anaerobic zone, (4) prethickening of sludge to prevent return of liquid from the anaerobic phase, (5) adjustment of the zones' arrangement to suit the nature of the organic compounds in the sewage, (6) control of dissolved oxygen in the aeration basin to minimize return of dissolved oxygen to the anoxic basin, (7) prevention of aeration of phosphorus-containing wasted sludge, (8) a retention time of 2.5 hours in the anaerobic basin, and (9) supplementary chemical additions if cost-effective. DEVELOPMENTS IN WASTEWATER HANDLING AT POWER PLANTS,
R. C. Rittenhouse.
Power Engineering, Vol 86, No 3, p 34-42, March, 1982. 2 Fig, 6 Tab.

Descriptors: *Powerplants, *Zero discharge, Wastewater treatment, Industrial wastewater, Waste treatment, Design criteria, Cooling towers, Evaporation, Water reuse, Thermal pollution, Monitoring.

Many options for wastewater handling systems at powerplants are available. The experiences at several zero discharge facilities, the efforts to reduce cooling tower blowdown, the problems of thermal

discharges, and recommendations for monitoring groundwater at powerplant disposal sites are presented. Retrofitting the operating Martin Drake Power Station, Colorado Springs, to produce zero discharge is described in detail. Designing a zero discharge system for a new plant is not limited by existing equipment capabilities. The wastewater system is so important that it should receive the same priority as the power block in the design stage. Zero discharge is not economically or environmentally feasible for every geographic area, and it must not be promoted as a cure-all or national goal for all powerplants. Other equipment can limit, rather than totally eliminate, waste discharges by side-stream softening, reuse of some streams as process water, and wet and dry scrubbers. Commercial methods available for reducing cooling tower blowdown are vapor-compression-evaporation, chemical softening in makeup and side-stream treatment modes, electrodialysis, and reverse osmosis. Some experimental methods are wet/dry cooling, indirect freeze concentration, foam-enhanced evaporation, and the magma cooling tower. There is much controversy in handling of thermal discharges, which in many cases have little or no adverse environmental effects, but must nevertheless be treated with expensive equipment. Proper handling of coal pile runoff, fly ash, bottom ash, and flue desulfurization wastes to prevent groundwater contamination are still being debated. (Cassar-FRC)

Descriptors: *Domestic wastes, *Water quality, *Waste disposal, *Impervious soils, *Septic tanks, Wastes, Wastewater treatment, Soils, Slopes, On-site tests, Flow rates, Flow characteristics, Water table rise, Septic wastewater, Wastewater absorption, Field capacity.

A method is proposed for sizing septic tank absorption fields by examining the effect of domestic waste on water quality and water table elevations. The necessity for thorough on-site evaluation of sloping impermeable soils such as those encountered in the study area is emphasized. On-site determinations were made on hydraulic conductivity, percolation, infiltration rates, and water quality. To characterize flow, it was necessary to ascertain the relation between design-flow rate and the water table rise in terms of soils and site parameters. A published method was used to determine the uniform flow depth on sloping soils which allowed the determination of the flow rate and on estimation of trench length to be made. This method showed good agreement with a standard method. Water quality studies suggested the principal ionic species in wells to be calcium, magnesium, sodium, and bicarbonate, and that most of the deep wells produce water from two different aquifers. In addition, most well water was found to be relatively hard, and nitrate and phosphorus were below EPA limits. However, the observed presence of fecal coliforms, apparently from adjacent septic systems, indicate a potential community health hazard. (Zielinski-MASIMA)

ANAEROBIC TREATMENT IN NOVEL CONTACT DIGESTER,
Duncan, Lagnese and Associates, Inc., Pittsburgh, PA.
J. A. Oleszkiwicz, and S. Koziarski.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 367-378, April, 1982. 8 Fig, 1 Tab, 15 Ref.

Descriptors: *Anaerobic conditions, *Wastewater treatment, Oxygen demand, Biochemical oxygen demand, Chemical oxygen demand, Industrial wastes, Animal wastes, Barn wastes.

Various methods of anaerobic digestion are compared as applied to the treatment of dilute piggery wastewaters from an industrial scale piggery. The work encompassed batch tests, studies in anaerobic flow-through digesters without sludge recycle, studies in contact digesters with continuous sludge recycle, and studies in upflow anaerobic biofilters. Specific attention is given to the results of the continuous sludge recycle reactors study, which was designed as a combined unit encompassing both vigorous jet mixing with digester gas and quiescent sludge blanket upflow biofiltration-clarification. The studies explored the lower limits of hydraulic retention time (HRT) and the upper limits of organic loadings to the reactor. Gas production and methane content were studied and compared with gas yields from the anaerobic flow-through digesters. Raw piggery waste substrate was used as feed with chemical oxygen demand contents of 13-14 g/liter. The studies demonstrated the feasibility of obtaining methanogenic conditions at HRT as low as 0.5 d and corresponging organic load of 38 kg COD/cubic meter/day. Satisfactory secondary treatment was attained at HRT of 3.5 day and a load of 4 kg COD/cubic meter/day, yielding steady state chemical oxygen demand removals in excess of 85% and filtered effluent COD and BOD of 1,200 and 500 mg oxygen/liter, respectively. The biogas production at that loading is 3.15 cubuc meters/day. 75% of which was methane, which corresponds to 0.17 cubic meters/kg COD removed. (Baker-FRC)

Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 349-366, April, 1982. 1 Fig, 6 Tab, 14 Ref.

Descriptors: *Activated sludge processes, *Optimization, Systems analysis, Planning, Wastewater treatment, Sludge, Algorithms, Mathematical studies.

The objective of the present paper is to present a concise, readily usable, and efficient method for performing cost optimization in the operation of the activated sludge system by using realistic models for the unit processes. A method has been presented for determining the minimum cost operation of an activated sludge wastewater treatment plant for several time periods. This method was applied to a plant in Erie County, New York. The method uses a search technique for discrete valued variables to optimize a nonlinear cost function for the operation of an activated sludge process. To present the method and computational procedures, an example activated sludge system is presented. The operation of the activated sludge process was formulated as an optimization problem with nonlinear cost functions and realistic models for the unit processes. A complex method of constrained optimization for discrete-valued variables is also presented, and an example problem is solved for an existing plant. The complex method proved to be an efficient procedure for determining the optimal operation of an activated sludge wastewater treatment system. The procedure allows the use of nonlinear objective function, nonlinear noncontinuous constraints, and noncontinuous variables. Therefore, realistic process models and actual physical constraints can be used. The optimal operation procedures are obtained directly from the algorithm. The algorithm is developed so that the operator can use it with the same input data and data format that he is generally accustomed to using. Inflows for each period of operation need to be included in the analysis. However, the analysis may now be done for several different inflow sequences to determine operation sensitivity to inflows. SEWERS AND CITIES: FRANCE AND THE UNITED STATES COMPARED,
National School of Bridges and Roads, Paris (France).
G. Dupuy, and J. A. Tarr.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 327-338, April, 1982. 13 Ref.

Descriptors: *Wastewater treatment, *Sewer systems, France, United States, Reviews, Public policy, Urban wastewater, Political aspects, Governmental interrelations, Public health, Federal jurisdiction, Wastewater disposal, Storm runoff, Public investment.

This article attempts to compare the development of technological systems for the removal and disposal of human wastes in France and the United States. The areas addressed include the motivations driving technological innovation in the waste removal and disposal area, factors affecting system choice, the development and impacts of systems, and the relative roles of government, professional groups, and the public in influencing decisions. It was concluded that innovations in the water and wastewater areas were often made without fully understanding either the operation of systems being replaced or the possible impacts of the innovation. The primary anticipatory failures concerned the impacts of urban water systems and the

LIBRARY U. OF I., URBANA-CHAMPAIGN

disposal of the wastewater generated. Sewerage technology transferred the locus of pollution and hazards to public health from the immediate locale to downstream or down-lake cities. The resulting political and policy conflict over water quality illustrates the difficulty in changing a capital-intensive technology, implemented for beneficial reasons, when the negative impacts of the technology are felt by second parties. The existence of an in-place capital intensive technology and the policy of dealing with its negative impacts by retrofit discouraged attempts to deal with the original problem by alternative means. Due to the transport of pollutants over political boundaries, wastewater technology resulted in an upward shift of governmental regulatory power from local to the state and federal levels. General societal values such as a belief in progess and technological optimism were integral to the acceptance of the technology. (Baker-FRC)

ROTATING BIODISKS RECARBONATE ALKALINE WASTEWATER,
Army Medical Bioengineering Research and Development Lab., Fort Detrick, MD.
C. I. Noss, R. D. Miller, and E. D. Smith.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 339-348, April, 1982. 5 Fig, 5 Tab, 7 Ref.

Descriptors: *Wastewater treatment, *Nitrification, Alkalinity, Phosphorus, Lime, Rotating biological contactor, Microorganisms.

A study was performed on phosphorus removal by low-level lime (pH 9.5) precipitation in the primary clarifier, followed by biological recarbonation using the rotating biological contactor (RBC) process. The enhancement of nitrification by a chemically induced increase in pH was also demonstrated. The desired goal was to determine if the microbial populations attached to an RBC could function under the stress of elevated pH. Uniform flow rates were applied, thereby eliminating diurnal flow variations which could have affected recarbonation during full-scale treatments. The low level lime addition resulted in high alkalinity in the RBC at an optimum pH for nitrification. It also reduced the biochemical oxygen demand (BOD) loading to the RBC, which should increase the media surface area available for nitrifying organisms. Recarbonation and phosphorus removal were achieved at hydraulic loadings of 2.0,3.0, and 4.0 gal/day/square foot (0.08,0.12, and 0.16 cubic meters/square meter/day), but organic substrate removal was less efficient and nitrification was far less efficient at high loading. Splitting the wastewater influent among RBC stages did not significantly alter the performance of this system. (Baker-FRC)

PHARMACEUTICAL WASTE TREATMENT BY ANAEROBIC FILTER,
Camp, Dresser and McKee, Inc., New York.
E. F. Sachs, J. C. Jennett, and M. C. Rand.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 297-314, April, 1982. 8 Fig, 3 Tab, 22 Ref.

Descriptors: *Wastewater treatment, *Filter media, Pharmaceutical industry, Organic compounds, Industrial wastes, Anaerobic conditions, Adsorbents, Biochemical oxygen demand, Oxygen demand.

A study was designed to investigate the physical characteristics, chemical composition, and variations of wastewater from chemically synthesized pharmaceutical production, apply that waste to the anaerobic filter and determine its treatability. The anaerobic filter sucessfully treated the pharmaceutical waste at an influent chemical oxygen demand (COD) condentration of 2,000 mg/liter when operated at 35 degrees C utilizing a 36 hour hydraulic retention time, while producing constant COD removal efficiencies of 70-80% and biochemical oxygen demand (BOD) removals of 94%. The anaerobic filter exceeded the performance of the existing treatment scheme by 33% in terms of lb COD/1,000 cubic feet/day removed, and also greatly reduced the effluent color. The anaerobic filter could not withstand a threefold concentration increase as a shock loading as evidenced by 18% COD and 25% BOD reductions while feeding an influent COD concentration of 6000 mg/liter at a 36 hr hydraulic retention time. The anaerobic filter proved very useful as a pretreatment device for the treatment of chemically synthesized pharmaceutical waste. Low cellular synthesis rates and long solids retention times enable it to treat waste efficiently without the need for solids wasting. (Baker-FRC)

TREATABILITY OF TYPE A ZEOLITE IN WASTEWATER--PART I,
Procter and Gamble Co., Cincinnati, OH.
J. E. King, W. D. Hopping, and W. F. Holman.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2875-2886, December, 1980. 5 Fig, 5 Tab, 26 Ref.

Descriptors: *Zeolite, *Sewer systems, *Suspended solids, *Primary treatment, Detergents, Activated sludge process, Trickling filters, Wastewater treatment, Trace metals, Coagulation, Plumbing.

Type A Zeolite, a silica-alumina detergent builder with a particle size of 3-4 microns, did not accumulate in wastewater collection systems or adversely affect primary of secondary treatment processes. The sodium form of this agent is present in laundry formulations and the calcium form in wastewater. Testing was performed with concentrations of zeolite considerably higher than the 10 mg per liter expected under normal conditions. Examination of washing machine plumbing made of copper, iron, and polyvinyl chloride revealed only a very thin layer at some locations, apparently as a function of roughness, after a equivalent of 4-5 months of average home washing machine use. Sink traps contained no deposits ascribable to Zeolite Type A. Sewer lines in a village where 75 of 109 households used Zeolite Type A detergents had small amounts of the builder in the surface sediment layer. No long term accumulation or flow impairment was likely. In settling tests which modeled primary treatment, Type A Zeolite was removed with the other suspended solids. Model activated sludge and trickling filter processes removed 98% of the Zeolite; full-scale processes would probably be 80% effective. Both the smallest size fraction and the bulk material were removed to the extent of 97-98% by primary treatment and activated sludge-secondary clarification. Addition of ferric chloride, alum, or lime removed nearly 100% of the zeolite compared with 33-72% without chemical treatment. The activated sludge treatment of linear alkylbenzene sulfonate was not affected by addition of the Ca form zeolite up to 444 mg per liter. Effluent concentrations of trace metals were not adversely affected by the presence of the zeolite. (Cassar-FRC)

TREATABILITY OF TYPE A ZEOLITE IN WASTEWATER--PART II,
Procter and Gamble Co., Cincinnati, OH.
W. F. Holman, and W. D. Hopping.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2887-2905, December, 1980. 12 Fig, 11 Tab, 25 Ref.

Descriptors: *Zeolite, *Septic tanks, *Sludge conditioning, *Suspended solids, Settling velocity, Detergents, *Wastewater treatment, Percolation, Sludge thickening, Activated sludge, Anaerobic digestion, Dewatering.

The presence of the detergent builder, Type A Zeolite, in wastewater did not adversely affect sludge treatment processes or home wastewater treatment systems. The settling velocity of activated sludge was doubled at zeolite concentrations up to 20% of suspended solids (SS). The following processes were not adversely affected by zeolite: anaerobic digestion of sludge (up to 20% of SS); dewatering properties of unconditioned activated sludge (up to 53% of SS); dewatering properties of unconditioned anaerobic digester sludge (up to 20% of SS); and dewatering properties of chemically conditioned activated and anaerobic digester sludges (up to 20% of SS). The dosage of conditioning chemicals was not affected at zeolite concentrations up to 10% of SS. Laboratory septic tank units removed > 97% of the zeolite; field septic tanks, 81-88%. Process efficiencies, sludge volume, and soil percolation rate were not meaningfully affected. (Cassar-FRC)

EXAMINATION OF PROCESS PARAMETERS AFFECTING SLUDGE DEWATERING WITH A DIAPHRAGM FILTER PRESS,
K. A. Pietila, and P. J. Joubert.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1708-1716, December, 1981. 13 Fig, 5 Tab, 8 Ref.

Descriptors: *Sludge filters, *Dewatering, *Filtration, Sludge solids, Diaphragm filter press, *Wastewater treatment.

The diaphragm filter press for sludge dewatering is a two-step process--filtration and squeezing. It achieves the same % cake solids as the conventional presses but in only 15-25% of the time. Several process parameters were investigated in field tests at 11 treatment plants: cake solids, solids recovery, cake discharge characteristics, yield, feed solids, chemical dosage, filtration time, and squeeze time. As filtration time increased, cake solids decreased and sludge throughput increased. As squeeze time increased, cake solids increased and solids throughput decreased. As feed solids increased, cake solids and solids throughout increased with lower chemical requirements. As chemical dosage increased, cake solids and solids throughput increased. The diaphragm filter press has advantages over a conventional press: wide range of process flexibility and substantial reduction in chemical dosage. Proper cloth selection and cake discharge are necessary for maximum solids throughput. (Cassar-FRC)

MATERIALS BALANCE IN AERATED STATIC PILE COMPOSTING,
Science and Education Administration, Beltsville, MD.
L. J. Sikora, G. B. Willson, D. Colacicco, and J. F. Parr.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1702-1707, December, 1981. 4 Fig, 4 Tab, 12 Ref.

Descriptors: *Sludge cake, *Composting, *Aerobic conditions, Aeration, Decomposition, Sludge disposal, *Wastewater treatment.

Composting of wastewater sludge by the aerated static pile method was studied for a year to determine the material balance for design purposes. The pile base was 20 cu yd of used wood chips. Wood chip bulking agent (72 cu yd) was mixed with 30 tons of 22% solids sludge and covered with 64 cu yd of unscreened compost as a blanket. The dimensions of the pile were 45 ft x 18 ft x 8 ft. Aeration was provided for the 21-day cycle to produce temperatures averaging 80 C. Thirty tons of wastewater sludge filter cake produced 11.5 wet tons (27 cu yd) of screened compost. At each cycle about a third of the wood chips had to be replaced. The dry weight loss was 4.7 tons (11% of the initial dry weight) and the wet weight loss was 21 tons, equivalent to 5000 gal of water. (Cassar-FRC)

CRITERIA FOR ACHIEVING PATHOGEN DESTRUCTION DURING COMPOSTING,
Science and Education Administration, Beltsville, MD.
W. D. Burge, D. Colacicco, and W. N. Cramer.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1683-1690, December, 1981. 3 Fig, 1 Tab, 34 Ref.

Descriptors: *Composting, *Pathogens, *Coliphages, Fate of pollutants, Sludge, Viruses, Bacteria, Parasites, Coliforms, Enteric bacteria, Enteroviruses, Monitoring, Graphical methods, Wastewater treatment.

The f2 coliphage was a suitable indicator organism for determining the state of pathogen destruction in wastewater sludge compost piles. A literature search showed that this coliphage was more resistant to heat inactivation than any other enteric pathogen, except for some atypical mycobacteria. A family of curves was constructed relating time and temperature with logs of f2 inactivation. Direct determination of pathogens was not necessary. The degree of pathogen destruction was determined by monitoring compost pile temperatures at the coolest part of the pile, the toe or lower edge. To account for the temperature uncertainty inherent in composting sludge, a reduction of 15 logs of f2 concentration was suggested for complete pathogen destruction. (Cassar-FRC)

BIOFILTRATION DESIGN BASED ON VOLUMETRIC LOADING,
Research Inst. for Environmental Development, Wroclaw (Poland).
J. A. Oleszkiewicz.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2906-2913, December, 1980. 7 Fig, 1 Tab, 10 Ref.

Descriptors: *Biofilters, *Organic loading, *Oxygen uptake, Activated sludge process, Trickling filters, Kinetics, Model studies, Mathematical models, *Wastewater treatment, Biological wastewater treatment, Industrial wastewater.

A model equating removal efficiency in biofilters to an exponential function of organic loading was shown to be applicable in cases where the Eckenfelder model gives insufficient correlation. The activated sludge and trickling filter models based on applied organic loading were shown to converge. The autooxidation coefficients were directly proportional to the biological activity of the slime and increased whenever slime showed increases in oxygen consumption. (Cassar-FRC)

SEPTAGE AND WASTEWATER TREATMENT IN THE ACTIVATED SLUDGE PROCESS,
Lowell Univ., MA.
B. A. Segall, and C. R. Ott.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2655-2665, November, 1980. 4 Fig, 8 Tab, 3 Ref.

Descriptors: *Municipal wastewater, *Design criteria, *Wastewater management, *Septic sludge, *Organic loading, Municipal wastes, Activated sludge, Clarifiers, Dissolved oxygen, Separation techniques, Wastewater treatment, Solid wastes.

Since septage is generally not accepted by municipal wastewater treatment plants in the Commonwealth of Massachusetts, this type of waste is discharged directly to land and surface waters. A septage monitoring program was carried out at the large Marlboro Easterly Wastewater Treatment Plant to determine feasible septage capacities for wastewater treatment facilities. Treatment cost and effluent quality were also examined. Results showed that a 2% addition of septage, on the average, doubles solids and organic loading on the treatment facility. Septage organic and solids content can be removed by a conventional activated sludge process. Septage did not markedly change oxygen utilization rates nor cause excessive short circuiting at feeding rates of 37% of the design flow rate and at wastewater flow within the design rate. Accumulation of anaerobic solids at the bottom can cause sludge upsets, especially during the summer months. In designing clarifiers for combined wastewater and septage solids removal, effluent quality, sludge removal, and surface skimming are critical. While septage seems to enhance settling and removal efficiency, particular attention should be paid to the skimming mechanism design. Fast removal of settled solids requires adequate pump and dewatering capacity. (Geiger-FRC)

EFFECTS OF CHEMICAL ADDITION ON THE PERFORMANCE OF SETTLING TANKS,
Toronto Univ. (Ontario). Dept. of Civil Engineering.
G. W. Heinke, A. J. Tay, and M. A. Qazi.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2946-2954, December, 1980. 5 Fig, 5 Tab, 17 Ref.

Descriptors: *Primary treatment, *Settling tanks, *Coagulation, *Wastewater treatment, Ferric chloride, Polymers, Design criteria, Suspended solids, Biological oxygen demand, Phosphorus removal.

Addition of ferric chloride and polymers to wastewater primary treatment tanks for the purpose of phosphorus removal produced secondary benefits. A 4-year study at three Ontario treatment plants revealed that chemical addition caused suspensions to settle more quickly. In design of new plants, smaller tanks may be used; for existing plants the settling tank capacity is substantially increased, avoiding or delaying expansion. BOD and suspended solids removal in the primary stage was enhanced. In some cases effluent was of high enough quality to discharge without further treatment. In others the load to the secondary system was greatly decreased. Costs for the chemicals were offset by decreases in capital costs for the primary and secondary treatment plants. However, more sludge was produced by the chemical addition. The following tentative design guidelines were proposed for primary horizontal-flow clarifiers treating domestic wastewater: design flow rate of 1.5 to 2.0 times the average daily flow, detention tiimes of 10-30 min with chemical addition and 20-45 min without, overflow rate of < 1.2 liters per sq m per sec under maximum flow conditions, velocity of < 8 ft per min under maximum flow conditions, and suspended solids removal efficiency of 70% with ferric chloride, 85% with ferric chloride plus polymer, and 40-50% with no chemical addition. THE XIII OLYMPIC GAMES AND ENVIRONMENTAL QUALITY PERSPECTIVE,
D. A. Corliss, and K. Freiling.
Clearwaters, Vol 10, No 2, p 6-7, 9, June, 1980.

Descriptors: *Environmental effects, *Slope stabilization, *Wastewater treatment, Lake Placid, Olympic Games, New York, Soil stabilization, Sludge disposal, Erosion, Recreation wastes, *Waste disposal.

Waste disposal at Lake Placid, New York, during the Winter Olympic Games in 1980 had a minimal environmental impact. Sediment generated during construction caused stream load violations on numerous occasions. The problem was solved by using a properly designed and maintained sedimentation basin, and, on slopes, jute mesh, slope stabilization, and seeding. Portable toilet wastes were hauled to the Lake Placid treatment plant for treatment. Although a 10,000 gal holding tank was planned to control silver-containing photographic developing wastes from the Kodak film processing installation, it was not necessary because a silver recovery system was installed. Receiving streams were monitored continuously during the Olympic period. Flow in Lake Placid's treatment plant (2.5 mgd design capacity and 1.0 mgd normal winter flow) averaged 1.5-1.98 mgd during the peak period. Effluent COD did not exceed 120 mg per liter on any day. LAND APPLICATION OF SECONDARY EFFLUENT AT LAKE GEORGE, NY,
D. B. Aulenbach, and N. L. Clesceri.
Clearwaters, Vol 10, No 2, p 16-21, June, 1980. 3 Fig, 2 Tab, 3 Ref.

Descriptors: *Land application, *Tertiary wastewater treatment, *Sand filters, Lake George, New York, Wastewater treatment, Filtration, Trickling filters, Recreation wastes, Infiltration, Water quality, Nutrients, Nitrates, Phosphates, Environmental effects.

Since 1939 secondary effluent from the resort community of Lake George, New York has been successfully treated without chlorination by application to natural delta sand by intermittent dosing using the rapid infiltration technique. The system consists of sedimentation, sludge digestion, trickling filter treatment, secondary sedimentation, and land application. At present the maximum daily summer flows approach 1.3 mgd, near the treatment plant design capacity of 1.75 mgd. Occasionally all the sand beds are full and effluent is applied to beds in an adjacent field. If both force main pumps are running simultaneously, the flow reaches 2.5 mgd. This creates turbulent flow in the primary settling tanks and increases the suspended solids load to the trickling filters. In spite of temperatures s low as -30 F and occasional ice cover, the sand beds function satiffactorily. Infiltration rates vary between 0.3 and 1 ft per day. Immediately after cleaning (scraping, discing, and releveling) infiltration rates of 2.5 ft per day are observed. Average annual application is 63% of infiltration capacity for a slow bed and 82% for a fast bed. During the extreme conditions of August 1976 (heavy rainfall at a time of peak sewage flow) 100% of capacity was reached. Since the water ultimately returns to Lake George via seepage into streams, water quality is monitored for nutrients and bacteria. Biodegradable matter, coliforms, and fecal streptococci are removed in the top of the sand. Viruses were not determined. The seepage water, of drinking water quality, contains 5-6 mg per liter more nitrate and 2 micrograms per liter more otheophosphate than background levels of the local groundwater. (Cassar-FRC)

DIE-AWAY KINETICS OF AEROSOLIZED BACTERIA FROM SPRINKLER APPLICATION OF WASTEWATER,
Hebrew Univ., Jerusalem (Israel). School of Applied Science and Technology.
B. Teltsch, H. I. Shuval, and J. Tadmor.
Applied and Environmental Microbiology, Vol 39, No 6, p 1191-1197, June, 1980. 4 Fig, 2 Tab, 25 Ref.

Descriptors: *Wastewater disposal, *Land disposal, *Bacteria, Mortality, Pathogens, Escherichia coli, Mathematical equations, Aeration, Aerosols, Public health, Wastewater treatment.

Increased emphasis on wastewater reuse and disposal by land treatment has emphasized the need for a means of predicting the concentration of aerosolized pathogenic microorganisms downwind from the wastewater spray or aeration site. Wastewater treatment processes involving aeration can lead to the formation of aerosols which contain concentrations of enteric microorganisms 100 times or more greater than that detected in the ambient liquid. This paper presents a methodology for estimating, under field conditions, the microbial die-away constant. This constant may be used in predicting the aerosolized pathogenic microorganism concentrations downwind from a spray or aeration site by means of modified atmospheric diffusion equations. Experiments conducted using Escherichia coli labeled with tritium demonstrated that there was a much slower rate of bacterial die-away in the morning than in the afternoon, when the meteorological conditions were more hostile to airborne bacteria. SEWAGE PUMPING STATION SPLIT FOR MAINTENANCE,
Wilson and Co., Witchita, KS.
J. C. Dowell, and S. Wood.
Amerocan City and County, Vol 97, No 4, p 60-61, April, 1982. 1 Fig.

Descriptors: *Pumping plants, *Maintenance, Pumps, Wastewater treatment, Wichita, Kansas.

A dual-flow design permits half of the Wichita, Kansas, sewage pumping station to be shut down for maintenance and repairs while the other half continues to operate. The 160 mgd plant receives 35 mgd of bar-screened raw sewage during normal dry weather service. Each half of the pumping station contains a 17 ft wide, 22 ft long, 16 maximum depth wet well, four 24 inch sewage pumps (2 constant speed drive and 2 variable speed drive). The constant speed pumps are used only during wet weather flow. This arrangement is expected to handle growth in volume for the next 20 years. (Cassar-FRC)

'COMPUTERIZED' MEANS COST-EFFECTIVE FOR SEWAGE TREATMENT,
Thorn Creek Basin Sanitary District Water, Chicago Heights, IL.
R. A. Davis, and J. L. Daugherty.
American City and County, Vol 97, No 3, p 39-44, March, 1982.

Descriptors: *Computers, *Control systems, *Automation, *Wastewater treatment, Thorn Creek Basin Sanitary District, Chicago Heights, Illinois.

A computerized system was installed in the Thorn Creek Basin Sanitary District's advanced treatment plant in Chicago Heights, Illinois. The high speed digital processor is supported by printers, a remote station, and a color cathode ray tube display console. The computer logs all types of data as required and produces a 31-page monthly report. It supervises many operations including calculations, pumping, running blowers, chlorination, and flow control. A large variety of information is readily available for example, inputs and outputs, alarm occurrences, laboratory data, equipment status, and simulations. A computer system can save money through centalization of equipment, extended service life of equipment, manpower reduction, and energy conservation. (Cassar-FRC)

Descriptors: *Uranium, *Biomass, Adsorption, Heavy metals, Wastewater treatment, Microorganisms, Industrial wastewater, Fungi, *Rhizopus.

This article presents an account of the work which led to the formation of a hypothesis on the mechanism of uranium biosorption by inactive Rhizopus arrhizus biomass. Experimental techniques used in the study included electron microscopy, x-ray energy dispersion analysis, and infrared spectroscopy, and supporting evidence was obtained for a biosorption mechanism consisting of at least three processes. Uranium coordination and adsorption in the cell wall chitin structure occurred simultaneously and rapidly, whereas precipitation of uranyl hydroxide within the chitin micro-crystalline cell wall structure took place at a lower rate. Interference of iron and zinc coions with uranium biosorption was indicated. Interference with any of these three processes can affect negatively the overall uranium biosorptive uptake. Such interference could involve the blocking of chitin amine nitrogen by other ions forming complexes or the increase in solubility of the adsorbate by changing the solution acidity. Uranium biosorption by inactive R. arrhizus is clearly a physicochemcial process with a considerable potential for technical applications, including industrial wastewater treatment. (Baker-FRC)

AN OVERVIEW OF POROUS PAVEMENT RESEARCH,
Municipal Environmental Research Lab., Edison, NJ. Storm and Combined Sewer Section.
R. Field, H. Masters, and M. Singer.
Water Resources Bulletin, Vol 18, No 2, p 265-270, April, 1982. 3 Fig, 8 Ref.

Descriptors: *Storm water, *Paving, *Urban runoff, *Porous media, Asphaltic concrete, Concretes, Water management, Runoff volume, Design criteria, Recharge, Groundwater recharge, Drainage.

Porous pavement is a storm water management technique usable on parking lots and low traffic roadways to reduce runoff volume and pollution while increasing groundwater recharge. Cost reductions can result from elimination of curbs, drains, and small storm sewers. Porous asphalt pavements are a thin layer (0.75-1 inch) of open graded asphalt concrete mix overlying a deep base of large crushed stones. The surface coat has a coarse texture and a high void space ratio. This structure allows water to quickly enter the crushed stone layer, where it gradually drains to the subbase or in a lateral direction. Other surfaces include concrete lattice blocks and porous concrete. Each design situation is unique. However, a few general design suggestions can be mentioned. Most soils, with proper drainage, will be suitable. The base aggregate must be hard, durable, and angular. The surface aggregate should be 2 inches of 0.5 inch crushed stone. The porous asphalt concrete surface layer has a void volume of 16%. The asphalt is 50 to 100 penetration grade, according to climate, and 5.5 to 6% of total pavement weight. Current research programs are described. One concerns the long-term structural integrity of pavements under severe environmental conditions, and the other compares different types of porous pavement construction. (Cassar-FRC)

TRACKING SEASONAL LOAD VARIATIONS,
Worcester County Sanitary District, MD.
N. Connell.
Water/Engineering and Management, Vol 129, No 3, p 52, 54, March, 1982. 3 Fig.

Descriptors: *Wastewater treatment, *Seasonal variations, Water treatment facilities, Design criteria, Ocean City, Maryland, Tourism.

A serious problem in municipal wastewater treatment plants in resort areas is seasonal load variation. A primary treatment plant was designed for Worcester County Sanitary District at Ocean City, Maryland, to deal with this problem. New clarifiers with sludge withdrawal circuits for continuously seeding upstream aeration tanks are key elements in the design modifications. Primary treatment begins when the raw influent from the community enters a large grit chamber which channels the flow to a wet well and pump station for distribution to two inverted-siphon clarifiers. Automatic skimmers traverse the periphery of the clarifiers every 44 minutes, removing oil and scum to scum tanks. The underflow continues on to thickeners. In summer the thickener underflow is fed to a disintegrator. In winter the underflow is piped to two clarigesters - combination units promoting clarification and digestion. Off-season storage of sludge provides frequent breaks for inspection and maintenance of plant equipment. During the summer of 1976 the plant incinerated about 473,200 lb of dry solids. The oxygen waste-activated sludge process secondary treatment system was added to the Ocean City facility in March of 1981. System biomass is broken into three trains capable of handling a summer seasonal maximum of 12 mgd. In winter this drops to as low as 2 mgd. Thus process engineering efforts have successfully met the problem of seasonal waste load variation in Ocean City. A clean outfall is now discharged directly to the Atlantic Ocean and an inert biomass is trucked to a regional Maryland storage lagoon for injection to crop lands. (Baker-FRC)

RIGHT VELOCITY KEEPS THE SOLIDS UP,
Garland Wastewater Treatment Dept., TX.
B. Cook.
Water/Engineering and Management, Vol 129, No 3, p 49-50, March, 1982. 3 Fig.

Descriptors: *Wastewater treatment, *Water treatment facilities, Equalizing basins, Basins, Equalizing reservoirs, Balancing reservoirs, Construction, Design criteria.

The Duck Creek Wastewater Treatment Plant in Garland, Texas, features an oval equalization basin more than four times the length of a football field, surrounded by a sloping embankment resembling a stadium grandstand. The basin provides fully controlled flow of the wastewater to the plant, which incorporates both biological and chemical treatment. Flow control substantially reduces the quantities of chemicals used in the process and generates significant savings. About 25% of the wastewater is industrial. With a peak capacity of 30 mgd and a daily average flow of 15.5 mgd, the plant serves a population of about 100,000. Influent enters the equalization basin untreated. The basin acts as a surge facility to ensure controlled flow, as well as keeping the grit, sand and other solids suspended in the wastewater. It also introduces air to provide an adequate dissolved oxygen content. Wastewater flows from the basin through a grit chamber and bar screens, then into a pumping station where the flow is split into two streams. One stream is directed to a biological activated sludge treatment facility and the other through a chemical treatment plant incorporating four clarifiers with lime, ferric chloride and polymer injection for solids flocculation and settling. Wastewater is then piped to a recarbonation basin, where carbon dioxide lowers the high pH. It is then pumped through ultra-high rate mixed media filters and chlorinated for disinfection before discharge. Flow from the biological treatment facility joins the chemically treated stream before chlorination. (Baker-FRC)

SAVING WATER SCENICALLY,
Camp, Dresser, and McKee, Inc., Albuquerque, NM.
J. Burgh.
Water/Engineering and Management, Vol 129, No 3, p 46-47, March, 1982. 1 Fig.

Descriptors: *Water conservation, *Aesthetics, *Wastewater treatment, Design criteria, Construction, Wastewater facilities, Water treatment facilities, Wastewater renovation, Water reuse, Tourism.

An unusual wastewater reclamation system tailored to stringent site, recreational and aesthetic constraints was installed at the Bishop's Lodge resort in New Mexico. Designed to be an integral part of the resort, the system provides secondary treatment through a packaged extended-aeration plant. Effluent is either used for pasture irrigation or passed through pressure filtration and a pool and waterfall display which provides further aeration and exposure to sunlight. Water supply in this area of the country has always been limited, with an annual precipitation rate averaging only 13 inches. Tourists pass the treatment facility site, and therefore odors, noise and visual nuisances had to be strictly controlled. The potential for nitrate contamination of the valley's groundwater was an important consideration. An extremely short construction season had also to be considered. The arrangement as designed not only blends into the natural terrain, but also complements the riding and hiking trails. The secondary treatment unit is screened from view by means of earth mounds and plantings. Surrounding the pool system are foot

paths for strolling, and one of the principal pack trails crosses through a waterfall halfway up the hillside. Effluent is circulated through the pool system 8 to 12 times per day during the sunlight hours. Polished effluent is pumped to the lawn irrigation system. Similar systems were designed by the same architect for Disneyland, Disneyworld, and Busch Gardens. (Baker-FRC)

DEEP SHAFT,
J. Lock.
Water/Engineering and Management, Vol 129, No 3, p 57-58, 60, 62, March, 1982. 4 Fig.

Descriptors: *Wastewater treatment, *Design criteria, Water treatment facilities, London, England, Construction, Deep shaft process.

A Deep Shaft effluent treatment plant has been in operation since early 1978 at Marsh Farm Sewage Treatment Plant in Tilbury on the Thames, east of London, England. Four major benefits of deep shaft treatment are: primary settlement of the sewage is not needed, the sludge produced is able to be disposed without further treatment, real estate requirements are minimal, and environmental impact is easily controlled. One of the major requirements to make the process competitive with natural products was economy of scale; this was achieved by building a very large single stream plant. At its heart is the pressure cycle fermenter, designed for an annual output of 55,000 to 65,000 tons of dried product. Volume in the Deep Shaft process is dictated by the biodegradability of the wastewater to be treated rather than by oxygen transfer characteristics. The heart of the process is the deep shaft itself, with its head tank, from which nitrogen, oxygen and carbon dioxide bubbles rising from the shaft are released. Circulation of the liquid in the shaft is brought about by injecting air mainly or wholly into the downcomer. Since installation of the Shaft, the Anglian Water Authority has undertaken a series of studies to prove its ability to meet the design criteria and to determine the optimum process parameters for maximum and predictable performance. Start-up problems have included flow reversal, foaming, shaft ventilation, and blockages. (Baker-FRC)

RELIABILITY OF ON-SITE SEWAGE DISPOSAL SYSTEMS IN FAIRFAX COUNTY, VIRGINIA,
Fairfax County Div. of Environmental Health, VA.
J. O. Bowman.
Journal of Environmental Health, Vol 44, No 5, p 249-252, March-April, 1982. 1 Fig, 2 Tab, 3 Ref.

Descriptors: *Wastewater disposal, *Septic tanks, Wastewater treatment, Septic wastewater, Environmental effects, *Virginia, Fairfax County.

In 1979 a study was made of on-site sewage disposal systems in the area of Fairfax County, Virginia, which had been installed between 1952 and 1978. The typical on-site system in this study consists of a septic tank, distribution box and soil absorption trenches. A typical system installed in 1955 served a three bedroom dwelling and consisted of 400 lineal feet of absorption trench. The typical system 20 years later served a four bedroom dwelling and consisted of a 1480 gallon septic tank with 480 lineal feet of absorption trenches. The increase in the size of the septic tank was due primarily to the popularity of garbage disposal devices and the requirement that all systems be designed for such devices. The study in 1979 showed that of the 1013 systems installed between 1952 and 1958, 96% were operational at the end of 20 years after installation and had not experienced any malfunctions. While the potential life of an on-site sewage disposal system is not known, the study revealed that of 62 systems installed in 1952, 97% have functioned satisfactorily for 27 years. Of the 110 systems which malfunctioned, the peak period for such occurrences was between the 11th and 18th year, with 47% occurring during this period. Seven systems were identified in which the malfunctions were attributed to soil clogging; the average period prior to this occurrence was 18.4 years. It was concluded that on-site sewage disposal systems for small wastewater flows offer a reliable method of disposal with minimal environmental impact. (Baker-FRC)

ROLE OF SURFACE ACTIVE MEDIA IN ANAEROBIC FILTERS,
Burk and Associates, Inc., New Orleans, LA.
K. A. Khan, M. T. Suidan, and W. H. Cross.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 269-285, April, 1982. 8 Fig, 3 Tab, 22 Ref.

Descriptors: *Anaerobic conditions, *Filter media, Activated carbon, Adsorbents, Coal, Wastewater treatment, Water treatment, Chemical oxygen demand, Oxygen demand.

The objectives of this study were to determine whether surface active granular activated carbon provides a better packing medium than nonporous anthracite coal for the anaerobic filter. The wastewaters used in the study included both synthetic wastewaters and a commercial aircraft paint-stripping wastewater. The organic content of the synthetic wastewaters included the readily degradable but poorly adsorbable glucose, the more biologically resistant, strongly adsorbable phenol, and combinations of the two organic nutrients. The glucose-bearing substrate was selected to minimize the adsorptive concentration polarization advantage of the activated carbon, while phenol was used to evaluate the role of substrate concentration polarization induced by the carbon surfaces. The response of the two filters under dynamic loading conditions of the phenol substrate was also evaluated. Throughout all phases of the study, the granular activated carbon packed filter out-performed the anthracite packed filter in terms of reduction of feed organic matter, methane production, and biomass retention. The granular activated carbon packed column resulted in a methane yield of 70.3% of the reduced dissolved chemical oxygen demand (DCOD), while only 38.5% of the reduced DCOD was converted to methane in the anthracite packed column. The DCOD and DOC conversion efficiencies obtained from the anthracite-packed column were 69 and 58%, respectively. An additional advantage of the carbon medium appears to be its biomass retention characteristics. (Baker-FRC)

HYDRAULIC REGIME AND ACTIVATED SLUDGE PERFORMANCE,
Ohio State Univ., Columbus. Dept. of Civil Engineering.
R. M. Sykes.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 286-296, April, 1982. 19 Ref.

Descriptors: *Activated sludge process, *Model studies, Biological oxygen demand, Chemical oxygen demand, Oxygen demand, Microorganisms, Sludge, Wastewater treatment.

An alternative to the standard bio-kinetic theory is presented to describe the activated sludge process. This new method identifies the effluent soluble organic matter (SOM) as a product synthesized and excreted by the microbes of the activated sludge. This model predicts that all aeration tanks treating a given wastewater will produce the same effluent SOM concentration if they contain the same total biomass and are operated at the same solids retention time (SRT). This alternative model also predicts that the effluent SOM concentration will be proportional to the influent organic matter concentration, that the apparent microbial decay rate will vary as different nutrients are considered, and that plots of the specific uptake rate versus the effluent SOM concentration will show a positive SOM intercept. All these predictions were supported by experiment. (Baker-FRC)

Descriptors: *Combined sewer overflows, *Water treatment, Overflow, Sewer systems, Rainfall, Concentrator, Design criteria.

An analysis was made of a treatment device for pluvial water, as proposed by the American Public Works Association. The characterization of the convective-diffusive process is done by measuring the transit-time distribution of fluid and liquid particles. The study of similarity law done on two hydrualic models observes the critical velocity of solid particles as a similarity parameter. The device is called a swirl concentrator. The analysis showed that its efficiency greatly depends on a large eddy structure generated by an obstacle placed so as to obtain a usable hydraulic load-discharge characteristic. This large eddy structure is one of the most important phenomena in the efficiency obtained for the device. This has two effects on studies made on swirl concentrators. First the behavior is better characterized by the critical velocity of solid particles because of the resuspension of deposited solids. Second, it is possible to propose an obstacle configuration which increases the efficiency of the swirl concentrator. This configuration is on the basis of vertical bars put into the device. In swirl concentrators already built, the addition of such a pattern of bars improves the efficiency. (Baker-FRC)

CHEMOMETRIC MODELING OF WASTEWATER TREATMENT PROCESSE,
Ford Motor Co., Dearborn, MI.
D. Schuetzle, J. R. Koskinen, and F. L. Horsfall, III.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 457-465, May, 1982. 5 Fig, 5 Tab, 33 Ref.

Descriptors: *Biological oxygen demand, *Statstical analysis, *Prediction, Wastewater treatment, Model studies, Chemometric methods, Nitrates, Phosphates, Suspended solids, Trace metals, Temperature effects.

Chemometric methods (pattern recognition) and multivariate analysis were used in modeling a complex lagoon system treating a wastewater containing petroleum oil, glycols, and esters. BOD was correlated with 19 other parameters, 6 describing input and 13 describing output. Data obtained from 166 days of operation were used to develop a model to predict BOD for the following 81 days. Accuracy of the prediction was an average of 87%. The most significant parameters that controlled prediction of BOD levels were minimum temperature, suspended solids, calcium, magnesium, nitrate, iron, and phosphate. Optimum values for some of these (in mg per liter) were phosphate, 12; Ca, 150; Mg, 3; and Fe, 0.3. There was no relationshp between influent pH and BOD reduction. (Cassar-FRC)

LIBRARY U. OF L. URBANA-CHAMPAIGN

Descriptors: *Biological wastewater treatment, *Peformance evaluation, Oxygenation, Aeration, Dairy industry wastes, Industrial wastewaters, Oxidation, Organic matter, Biomass dynamics, Kinetics, chemical oxygen demand, Sludge, Settling velocity.

The objective of this study was to investigate the relative performances of three parallel rotating biological contractors in treating a synthetic milk waste by using air and pure oxygen under atmospheric or pressurized conditions. Performance parameters examined include acidity, dissolved oxygen, mixed liquor suspended solids, chemical oxygen demand reductions, sludge settleability, microbial nature, effluent suspended solids, ammonium-nitrogen, and nitrate-nitrogen. The thicknesses of the biofilms developed on the disk surface were increased by pure oxygen under pressure. This in turn improves the chemical oxygen demand reduction, provided that the waste strength is high and the biofilms do not bridge over the disk clearance. Use of pure oxygen also greatly improves the sludge settleability and reduces the filamentous growth. However, laboratory data appear to indicate that an excessively high concentration of dissolved oxygen has an inhibitory effect on biological nitrification. (Baker-FRC)

FILTERABILITY OF ACTIVATED SLUDGE IN RESPONSE TO GROWTH CONDITIONS,
Pittsburgh Univ., PA. Dept. of Civil Engineering.
Y. C. Wu, E. D. Smith, and R. Novak.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 444-456, May, 1982. 20 fig, 2 Tab, 30 Ref.

Descriptors: *Activated sludge process, *Filtration, *Nitrogen, Wastewater treatment, Sludge conditioning, Dewatering, Microorganisms, Wastewater composition, Filamentous bacteria, Bacteria.

Growth of activated sludge under severe nitrogen limitation of the influent wastewater produced sludge with poor dewatering properties. The filtering properties were poor in the presence of long-length filamentous organisms, dispersed and pin-point flocs, and extracellular biopolymers. However, short-length attached filaments were beneficial to floc formation and sludge filtration. Sludge with the best filtering properties in pilot plant tests was grown at a sludge age of 14.2 days and food/microorganism ratio of 0.35 for N-deficient sludge. N-rich sludges required higher chemical conditioner doses than N-deficient sludge. The presence of extracellular biopolymers, a natural thickening agent, also reduced the conditioner requirements. MUNICIPAL POLLUTION ABATEMENT REPORT CARD: SIGNIFICANT PROGRESS,
Environmental Protection Agency, Washington, DC.
J. A. Chamblee.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 422-427, May, 1982. 2 Fig, 3 Tab.

Descriptors: *Municipal wastewater, *Capital costs, *Statistics, Wastewater treatment, Secondary wastewater treatment, Biological oxygen demand, Suspended solids, Grants, Clean Water Act, Economic aspects.

Municipal wastewater treatment statistics collected during a 1980 EPA survey show significant progress toward the nation's clean water goals. Compared with 1973, the total flow reaching treatment plants has increased 36% to 95,594 million cu m per day, BOD removal has increased 13% to 76.4%, solids removal has increased 11% to 79.6%, and dry sludge has increased 58% to 23,763 metric tons per day. The population served by treatment plants in 1980 was 156.7 million (70% of the total population), 8.5% more than in 1976. Those served by secondary treatment or better increased 25.3% since 1976 to 119.4 million (53% of population). Since 1976 the number of secondary plants has increased by 58.8% to 6852 and the number of plants that do not discharge, by 36.1%; to 1361. During 1973 to 1979 $20 billion in federal, state, and local funds and $6.3 billion in non-government funds were spent for capital improvements. By 1985 it is expected that flows reaching treatment plants will reach 28,000 mgd, an increase of 14%, and BOD removal and suspended solids removal efficiencies will have increased to 82.6% and 83.4%, respectively. (Cassar-FRC)

1980 NEEDS SURVEY: COMBINED SEWER SSITE STUDIES,
Water Resource Engineers, Gainesville, FL.
J. E. Scholl, and R. L. Wycoff.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 315-326, April, 1982. 8 Fig, 2 Tab, 8 Ref.

Descriptors: *Wastewater treatment, *Planning, Surveys, Data acquisition, Sewer systems, Economic aspects, Water treatment facilities, Costs, Environmental Protection Agency.

The Environmental Protection Agency is mandated to prepare a biennial estimate of the cost to achieve the goals of the Federal Water Pollution Control Act. Such an estimate requires conducting a survey. Sites for the survey are generally selected to provide a wide range of sizes of combined sewer systems and a representative distribution across the United States. The 1980 Needs Survey investigated 10 sites to develop transferable criteria, principles and relationships which could be applied nationwide to estimate the cost to construct publicly owned wet-weather pollution control facilities. The site studies were performed using a receiving water simulation program called the Continuous Stormwater Pollution Simulation System (CSPSS) and an economic optimization program called the Computer Optimized Stormwater Treatment (COST) program. For these 10 study sites it was found that three types of receiving water/urban area conditions existed with respect to dissolved oxygen concentrations. These were sites where no DO problem existed, sites where the problem could be solved with removal of various inputs, and sites where a DO problem remained. A direct link between the CSPSS receiving water analysis and COST program economic analysis was obtained. It was then possible to establish the combination of wet-weather pollution abatement alternatives which achieved the desired removal for the least total annual cost. (Baker-FRC)

5E. Ultimate Disposal Of Wastes

LAND DISPOSAL OF SLUDGE,
J. W. Cormack, F. J. Winter, and M. D. R. Riddell.
Public Works, Vol 113, No 2, p 42-44, 90, February, 1982. 3 Fig, 3 Tab.

Descriptors: *Land disposal, *Sludge disposal, *Landfills, Sanitary landfills, Waste dumps, Sludge, Wastewater treatment, Sludge utilization, Cost analysis, *Lake County, *Illinois.

The North Shore Sanitary District in Lake County, Illinois is located about 20 miles north of Chicago, adjacent to Lake Michigan. Wastewater is treated at three major advanced treatment plants, each providing biological nitrification, chemical precipitation of phosphorus, and effluent filtration. Raw and digested sludge are transported to Waukegan for dewatering and ultimate disposal in a landfill. A portion of the digested sludge is hauled by truck for use as soil conditioner and fertilizer during the growing season. Before selecting the site for the landfill, field tests were conducted to demonstrate the stability of the soil, and consultations were held with various members of government agencies and district staff so as to present detailed development and operating plans. Site preparations included demolition of existing minor buildings, installation of ten 30-foot deep groundwater monitoring wells, construction of a sludge delivery road, a 10,000 gallon leachate tank, a new well, and an access road, rerouting existing farm drainage tiles traversing the area, and constructing sod waterways to convey surface drainage through the project area to adjoining downstream land at existing runoff locations. The application of sludge on agricultural land is limited by the type of crop grown and the chemical constituents of the sludge, particularly heavy metals and nitrogen. Data suggest that nitrogen rather than heavy metal content is the limiting factor. Landspreading of a small amount of liquid digested sludge is significantly less costly than dewatering and landfilling the same sludge. The amount that can be landspread is limited by space and spreading equipment availabilities. (Baker-FRC)

IMPROVED THERMAL SLUDGE CONDITIONING BY TREATMENT WITH ACIDS AND BASES,
Union Carbide Corp., South Charleston, WV. Research and Development Dept.
G. M. Alsop, and R. A. Conway.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 146-152, February, 1982. 7 Fig, 6 Tab, 14 Ref.

Descriptors: *Sludge conditioning, *Dewatering, *Heat treatment, Acids, Bases, Pathogens, Coliforms, Bacteria, Zinc, Cadmium, Metals, Heavy metals, Filtration.

Temperature and reaction times for heat conditioning of sludge for dewatering were reduced by a base-heat-acid treatment. The laboratory-scale study used sludges with different characteristics, two petrochemical wastewater sludges and a domestic wastewater sludge. Although optimum conditions differed with the sludge properties, a typical conditioning process was treatment at pH 10 and 70 C for 60 seconds followed by reaction at initial pH of 3.5 and 90 C for 60 seconds. The first step extracts polymers from the cells, and the second modifies the cell surface and causes flocculation using the extracted polymers. This treatment produced only 50-60 mg per liter soluble organic carbon. Subsequent dewatering of the base-heat-acid conditioned sludge on a belt pressures (3-5 psig) produced 20-30% cake solids. The process reduced fecal coliforms from 2.3 million per 100 ml to zero. Odor in stored samples was almost negligible. Zn and Cd contents of sludge were reduced by 49% and 73%, respectively. Shear tests on the conditioned sludge showed that it was resistant to shearing and subject to less floc breakup during subsequent processing. Comparison with other sludge conditioning processes (FeCl-lime-filter press and polymer conditioning-basket centrifuge) showed similar capital costs and lower operating costs, $12 a ton vs. $18 and $19 a ton, respectively. Descriptors: *Monitoring, Data transmission, Remote sensing, *Water pollution prevention, *Radioactive wastes, Sensors, Data aquisition, *Nuclear powerplants, *Germany, Environmental protection, Water pollution control, Automation, Networks.

Nuclear power plants in the Federal Republic of Germany must apply for official permission to discharge radioactivity liquid wastes into receiving waters. In order to receive this permission the plant must be operated according to specific regulations. The Unterweser Nuclear Power Plant (KKU) is used as an example to demonstrate how the discharge of radioactive substances in a tidal river can be automatically monitored and controlled. The Nuclear Inspectorate is now making use of remote monitoring equipment to regulate the discharges of nuclear power stations and protect receiving waters of their surrounding environments. An automatic remote monitoring system is being installed in the KKU to check plant operation and levels of radioactive wastes in all possible receiving waters. The regulations laid down by the water authority extend from the receiving water to these measuring points. The KKU will be required to provide automatic data transmission to the water authority from all the designated measuring stations. (Geiger-FRC)

Journal of the Environmental Engineering Division, Proceedings of the Amercan Society of Civil Engineers, Vol 108, No EE1, p 204-209, February, 1982. 2 Fig, 2 Tab, 5 Ref.

Descriptors: *Mathematical models, *Land disposal, *Landfills, *Leaching, *Waste management, Mathematical studies, Waste disposal, Water quality control, Model studies, Waste dumps, Leachates, Infiltration, Percolation, Groundwater movement, Subsurface drainage.

A simple methodology for use in designing leachate collection systems for the containment of wastes at disposal sites is presented. The methodology concentrates specifically on the engineering of drain spacing and groundwater mounding. A mathematical model is derived which describes leachate mounding over a sloping clay liner. The model, although implicit and nonlinear, converges rapidly. Parameter sensitivities can be readily manipulated for specific applications and to explore the need for new data input requirements into the model. The model was applied to the problem of designing a collection system for a landfill, where the concern is the impact on the groundwater mounding during leachate recycle, versus after the recycle is completed. The model will be useful in exploring the impacts of alternative designs for leachate collection systems. (Geiger-FRC)

CALORIFIC VALUE OF WASTEWATER PLANT SLUDGES,
Marquette Univ., Milwaukee, WI.
A. E. Zanoni, and D. L. Mueller.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE1, p 187-195, February, 1982. 2 Fig, 3 Tab, 4 Ref.

Descriptors: *Calorimetry, *Sludge utilization, *Chemical oxygen demand, *Volatile solids, Wastewater treatment, Mathematical studies, Sludge, Digested sludge, Primary sludge, Municipal wastewater, *Energy sources, Sludge disposal.

The energy usage of a wastewater treatment plant is an important consideration in its design and operation. The calorific values of various sludges generated during wastewater processing may be established by an oxygen bomb calorimeter. The use of this instrument in smaller plants is not a very common practice. To aid in calorific determinations, the calorific values of a variety of municipal waste water plant sludges are presented. A method for correlating the calorific value of a sludge sample to the COD value was developed. This procedure was sufficient for estimating the calorific value of most municipal wastewater plant sludges with a high degree of reliability. Calorific values of sludges were also correlated to the percent volatile solids value to compare the present results with those of other researchers. The COD correlation proved more accurate than the volatile residue technique. It was suggested that the COD determination is inherently a more sensitive measure of the material which accounts for the calorific content of the sludge. (Geiger-FRC)

REVEGETATING STRIP-MINED LAND WITH MUNICIPAL SEWAGE SLUDGE,
Pennsylvania State Univ., Harrisburg. Dept. of Environmental Resources.
W. E. Sopper, and S. N. Kerr.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102484, Price codes: A08 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-182, October 1981. 7 p, 4 Fig, 7 Tab. S-804511.

Descriptors: *Revegetation, *Strip mines, *Sludge disposal, *Land disposal, *Water pollution control, Groundwater pollution, Soil water, Trace metals, Bacteria, Coal mines, Municipal wastewater, Erosion control, Percolating water, Mine wastes, Impaired water use.

The lack of vegetative cover on old strip mine sites contributes to pollution from both soil erosion and acid mine drainage. The use of municipal sludge to revegetate mined land in an environmentally acceptable manner was demonstrated on several 4-ha plots in the anthracite and bituminous coal mining regions of Pennsylvania. Three sites representative of abandoned, barren bituminous and anthracite mines were treated with various types of municipal sludge at high and low application rates, and broadcast seeded with a mixture of grasses and legumes. A monitoring system was installed at each demonstration site to determine the effects of the sludge application on the chemical and bacteriological quality of groundwater and soil percolate water, chemical properties of the soil, and quality and growth of vegetative cover. Data collected during the 3-year period indicate that the sludge applications ameliorated the harsh site conditions and resulted in a quick vegetative cover that completely stabilized the demonstration site. Each site's vegetative cover has persisted and improved each year since its establishment. Although sludge applications increased some trace metal concentrations in the vegetation, all concentrations were below plant tolerance levels. Sludge applications have had no significant adverse effect on the chemical or bacteriologically quality of soil percolate or groundwater. (Moore-SRC)

PILOT FIELD STUDIES OF FGD WASTE DISPOSAL AT LOUISVILLE GAS AND ELECTRIC,
Louisville Gas and Electric Co., KY.
R. VanNess, A. Plumley, N. Mohn, C. Ullrich, and D. Hagerty.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-105479, Price codes: A14 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S7-81-155, October 1981. 14 p, 8 Fig, 6 Tab, 10 Ref.

Descriptors: *Landfills, *Waste disposal, *Trace elements, *Groundwater pollution, *Leachates, Sludge, Land disposal, Soil contamination, Water pollution sources, Runoff, Permeability.

The most extensive commercial experience in flue gas desulfurization (FGD) to date has been with lime/limestone wet scrubbers. A major challenge associated with the commercial development of these systems is the disposal of large amounts of by-product sludge within the constraints of land and water quality regulations. Properly prepared landfill from FGD sludge/fly ash mixtures can prevent trace element contamination of underlying groundwater. Analyses of leachates from the series of landfill impoundments in this study show that trace elements on the Resource Conservation and Recovery Act (RCRA) list of contaminants were found in concentrations below those proposed to characterize hazardous or toxic wastes. Decreasing concentrations, with time, of trace contaminants were observed in both leachate and runoff samples obtained from the stabilized sludge mixtures. Small, synthetically lined, above-ground impoundments provided higher concentrations of trace contaminants than the subsurface impoundments since no attenuation by local soil was provided and vegetation that might minimize runoff was not established on these sites. Water samples from beneath larger subsurface impoundments indicated that the filtering action of soil aids in decreasing the concentration of contaminants reaching the ground water supply. Certain mixtures have undergone a fixation reaction, reducing the permeability and minimizing the release of moisture and contaminants to the surrounding soil. (Moore-SRC)

DISPOSING OF SEWAGE SLUDGE AT SEA,
S. H. Jenkins.
Marine Pollution Bulletin, Vol 13, No 2, p 37-39, February, 1982. 1 Tab.

Descriptors: *Sewage sludge, *Sludge disposal, *Ocean dumping, Environmental effects, *Regulations, Water pollution control, North Sea, *Germany.

A review of recent papers on sewage sludge disposal at sea shown that this problem is being handled by different methods according to national attitudes. The Federal Republic of Germany is planning to terminate all sludge disposal in the North Sea. The U.S. EPA's decision to prohibit sludge dumping in coastal waters has been challenged in light of conflicting evidence on its environmental effects. The United Kingdom disposes of sewage sludge at 13 ocean sites under annual licences granted by the Military of Agriculture, Fisheries, and Food. The effects of sludge dumping and pollution from rivers are carefully monitored by chemical analysis and bioassays to limit the undesirable elements to levels which can be absorbed by the sea without producing ecological damage. SLUDGE MANAGEMENT IN THE ROCKY MOUNTAIN STATE,

Library of the Urban Institute

Black and Veatch, Denver, CO.
M. J. Maxwell.
Water/Engineering and Management, Vol 128, No 12, pp 28-31, 56, 57, December, 1981. 4 Tab, 2 Fig.

Descriptors: *Sludge, *Sludge reconditioning, *Wastewater management, *Hydraulic capacity, Sludge drying, Aeration, Lagoon systems, Filtration, Aerobic digestion, Reclamation, Sludge cake, *Sludge disposal, Inventory, *Colorado, Sludge management.

A complete inventory of all municipal treatment plants in Colorado was carried out in 1980, to assess the status of wastewater sludge management in that state. More than half of the 318 municipal facilities are lagoon systems which do not routinely process sludge. Mechanical systems predominate in the Mountain Resort and Front Range areas, where land costs are high and population is dense. Most plants have ample reserve capacity. The most common sludge disposal method is land application. Less than 20 plants use mechanical thickening equipment. Most plants employ anaerobic digestion. About 70% of the plants which dewater sludge use drying beds. Three sludge stabilization processes, anaerobic digestion, aerobic digestion, and composting, are used in Colorado. (Titus-FRC)

PREDICTING FULL-SCALE BATCH THICKENER PERFORMANCE USING THE FROZEN-IMAGE CENTRIFUGE,
Water Research Centre, Stevenage (England).
C. F. Lockyear.
Effluent and Water Treatment Journal, Vol 21, No 12, p 560-563, December, 1981. 3 Fig, 2 Tab, 9 Ref.

Descriptors: *Sludge thickening, *Performance evaluation, *Centrifugation, Dewatering, Sludge drying, Prediction, Mathematical equations, *Wastewater treatment, *Sludge disposal.

Gravity thickening is a process commonly used to reduce the costs for treating and disposing of sewage sludges. The extreme variations in the characteristics of the sludge necessitate the use of laboratory characterization tests in operating and designing sludge treatment processes. The frozen-image centrifuge test is one such laboratory test. This technique uses a low speed centrifuge and involves observation of the change in the interface height between the sludge and the supernatant liquor. The experimental results are then used to calculate the change in solids concentration of the sludge with time and to predict the ultimate concentration achievable for a given height of sludge in a thickener. However, the technique does not provide information on the time needed to achieve these results. A new empirical equation is presented which links directly the time in a gravity thickener to achieve a particular concentration with the time in the frozen-image centrifuge to achieve the same concentration. This method can be used either to monitor the performance of full-scale thickeners or to design new units. (Carroll-FRC)

AN ASSESSMENT OF GEOTHERMAL DEVELOPMENT IN THE IMPERIAL VALLEY OF CALIFORNIA; VOLUME 2 - ENVIRONMENTAL CONTROL TECHNOLOGY,
California Univ., Livermore. Lawrence Livermore Lab.
G. Armantrout, N. Crow, P. Leitner, C. R. Molenkamp, and F. Stephens.
Department of Energy Report DOE/EV-0092, July 1980. 133 p, 24 Fig, 18 Tab, 93 Ref. Morris, W., and Hill, J., Eds. W-7405-ENG-48.

Descriptors: *Geothermal power, *Geothermal resources, *Environmental control, *Brine disposal, *Injection, Subsidence, Cooling towers, Water quality, Waste disposal, Scaling, Drilling, Water treatment, *Imperial Valley, California.

Based on energy production scenarios and predicted environmental impact levels, environmental controls applicable to abatement of hydrogen sulfide emissions, cooling tower drift, noise, liquid and solid wastes, and induced subsidence and seismicity were assessed. Several currently available and emerging hydrogen sulfide abatement technologies are applicable to power systems contemplated for the Imperial Valley. The environmental impact of cooling tower drift will be closely tied to the quality of cooling water supplies. Although significant technological progress has been achieved in reducing drift emissions, the efficiency of drift eliminators may be rapidly degraded if low quality water supplies are used. Noise emission is not expected to be an important environmental issue. Spent geothermal brine constitutes the largest volume of waste generated in geothermal power plant operations. Other liquid wastes include: cooling tower blow-down fluid, accidentally discharged brine, and accidentally spilled process chemicals. These liquid wastes, for the most part, are expected to be disposed of by subsurface injection. Solid waste sources include: well drilling and wellbore cleanout debris, separated solids from spent brine and cooling water treatment operations, solids from hydrogen sulfide abatement, geothermal scale, and a variety of wastes from evaporation ponds and treatment facilities. Subsurface injection of fluids is the primary control for managing induced subsidence. Careful maintenance of injection pressure is expected to control induced seismicity. (Moore-SRC)

MICROBIAL ECOSYSTEMS RESPONSIBLE FOR ANAEROBIC DIGESTION AND COMPOSTING,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Environmental Science.
M. S. Finstein, J. Cirello, D. J. Suler, M. L. Morris, and P. F. Strom.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2675-2685, November, 1980. 3 Tab, 47 Ref.

Descriptors: *Anaerobic digestion, *Composting, *Wastewater treatment, Sludge, *Waste disposal, *Activated sludge process, Microbial degradation, Microbiological studies.

The most significant features of the anaerobic digestion and composting ecosystems are summarized and compared specifically in relation to contemporary needs in sludge management. The course of microbial events in sludge is determined by the water content and the presence or absence of porous structure. Consequently, for anaerobic digestion, the sludge is processed in aqueous form, whereas for composting it is processed as a solid material. Anaerobic digestion involves the formation and release of gases, but no inward movement of ambient air. It is a continuous process. Batch processing is not practicable for large-scale operation. Composting involves the formation and liberation of carbon dioxide and water vapor, and unlike anaerobic digestion, requires the movement of ambient air into the mass. In understanding the biological processes at work, three groups of microbial functions are recognizable in anaerobic digestion: solubilization, acid formation, and methane production. The stability of the process as a whole is discussed. While anaerobic digestion and composting are intended to achieve almost identical goals, the mechanisms involved and the extent to which the goals are met differ. Anaerobic digestion is advantageous primarily in requiring less labor for materials handling and in producing methane. Composting is advantageous with respect to pathogen kill, process stability, decomposition of industrial compounds, drying and residue acceptability as related to aesthetic quality and ultimate disposal. Composting would appear to be the superior process for crowded areas where final disposal is on land. (Baker-FRC)

DRAINABILITY OF AEROBICALLY DIGESTED BIOLOGICAL SLUDGE FROM TEXTILE WASTE,
Auburn Univ., AL. Dept. of Civil Engineering.
J. R. Judkins, Jr., and M. L. Hatcher.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2955-2963, December, 1980. 11 Fig, 4 Tab, 11 Ref.

Descriptors: *Sludge digestion, *Textile mill wastes, *Dewatering, Sludge conditioning, *Sludge disposal, Sludge drying, Sludge thickening, Aerobic digestion, Digestion, Polyelectrolytes, Wastewater treatment, Activated sludge process.

Sludge from a textile finishing mill was aerobically digested in the laboratory. Two-thirds of the total BOD reduction of 75% was attained within the first 7 days. Volatile suspended solids were reduced by 16-34% in 21 days. The non-volatile suspended solids increased during the early stages of digestion and decreased by 19-57% in 21 days for the first batch of sludge and 1-14% in 29 days for the second batch of sludge. Results of dewaterability studies suggested that optimum drainability was achieved at solids detention times of 3-5 days. Increasing the digestion time beyond 5 days decreased drainability. Applying raw, undigested sludge directly to sand drying beds was a feasible process. The drainability was improved by adding a cationic polyelectrolyte. Increasing the dosage of polyelectrolyte slightly decreased the volume of total drainable water. Therefore, an optimum polymer dose will maximize sludge drainage rate without decreasing total drainable water. (Cassar-FRC)

HOW MUCH SEWAGE NITROGEN ON FOREST SOILS. A CASE HISTORY,
Florida Univ., Gainesville. School of Forest Resources.
H. Riekerk.
BioCycle, Vol 23, No 1, p 53-56, January-February, 1982. 2 Fig, 3 Tab, 15 Ref.

Descriptors: *Forest soils, *Land application, *Sludge disposal, Wastewater disposal, Nitrates, Sulfates, Seattle, Washington, Soil types, Fertilizers, Trees, Plant growth, Waterlogging.

Application of sewage sludge or watewater effluents to forested lands offers several advantages over application to cleared areas. Decomposition is slower under the humid conditions and has a less dramatic environmental impact. Excess moisture is readily removed by transpiration of the trees. Forest soils are usually of low quality and are remote from the human food chain. Even on a 25% slope 0.4 cm dry sludge can be applied without contaminating surface runoff. Nitrates are the main problem for groundwater contamination. Studies on application of sewage to forest soils showed that this is feasible, but the volume must be carefully controlled to avoid surface runoff on slopes, formation of wetlands in level areas, clogging of soil pores with fine particulates, or escape of ammonia into the air. Sludge, 150 to 300 dry tons per ha, was applied to 2 coniferous forest soils near Seattle, Washington, in 1974-77. All treatments significantly increased nitrate and sulfate levels in C-horizon leachates, except in the gravelly soil. The various experimental variables did not significantly affect the nitrate-N or sulfate-S content of output drainage. (Cassar-FRC)

TRENDS IN SLUDGE MANAGEMENT,
A. Jacobs.
Water/Engineering and Management, Vol 128, No 12, p 10, December, 1981.

Descriptors: Mercury, Polychlorinated biphenyls, Heavy metals, Legal aspects.

A study of ocean dumping of sludge is reviewed. In their recent report the National Advisory Committee on the Oceans and the Atmosphere (NACOA) recommended that ocean dumping should continue to be permitted under appropriate management control in areas where no unreasonable degradation of the marine environment results. It is believed that ocean contamination is caused primarily by sources other than sludge dumping. Methods for evaluating the costs and hazards of land-based alternatives are needed. At present, land application of sludge is increasing, as is research dealing with application rates, crop selection, and health effects. The Environmental Protection Agency is in litigation over their position that all ocean disposal should be eliminated. (Titus-FRC)

PRESSURE DISTRIBUTION DESIGN FOR SEPTIC TANK SYSTEMS,
Wisconsin Univ.-Madison. Dept. of Civil and Environmental Engineering.
R. J. Otis.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE1, p 123-140, February, 1982. 11 Fig, 3 Tab, 16 Ref.

Descriptors: *Septic tanks, *Design criteria, *Pressure distribution, Septic wastewater, Wastewater, Compaction, High pressure, Load distribution, Clogging.

This paper reviews the principles of pressure distribution network design and presents a simplified design procedure for septic tank systems. The use of pressure distribution networks has been limited primarily to mound systems and large soil adsorption fields. Their use is greatest in Wisconsin, where the networks were first developed. Most are employed in individual home systems, but several of them are employed in community and commercial systems designed for daily flows up to 30,000 gal. The length of service of these systems ranges from 9 years for the individual mound systems to 4 years for the large networks. Limited monitoring of the networks has indicated that this method of distribution retards the development of a clogging mat on the soil's infiltrative surface. Excavation of several systems did not reveal signs of a clogging mat even after 2 years of continuous operation. Mechanical failures have been infrequent. Of more than 500 networks in use in Wisconsin, less than 10 have malfunctioned, with none employing siphons. Pump switch failure is the most common problem, resulting in pump burnout. High quality corrosion proof switches have corrected this problem. One such system serves a butcher shop in which the waste has a high grease content. The grease passed through the septic tank and into the distribution network where it plugged the laterals. More frequent septage removal has corrected this problem. Another system serves an office building. It is not expected that pressure distribution networks will replace conventional designs. However, they are recommended for use in very rapidly permeable soils and soils with shallow restrictive horizons as well as mounds and large absorption field. (Baker-FRC)

INDUSTRIAL WASTE PRETREATMENT AND EPA CADMIUM LIMITATIONS,
Metropolitan Sanitary District of Greater Chicago, IL.
C. Lue-Hing, D. R. Zenz, B. Sawyer, E. Guth, and S. Whitebloom.
Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2538-2551, October, 1980. 4 Fig, 17 Tab, 9 Ref.

Descriptors: *Cadmium, *Effluent limitations, *Industrial wastewater, *Pretreatment of water, *Sludge, *Land disposal, Wastewater treatment, Hazardous materials, Industrial wastes, Waste disposal, Solid wastes, Regulations, Municipal wastewater, Water pollution sources, Pre-treatment standards, Domestic wastes.

The impact of the Solid Waste Disposal Act as it pertains to cadmium (Cd) levels on the treatment of municipal wastes is discussed. The feasibility of using industrial waste pretreatment regulations to reduce sludge Cd levels or allow reasonable sludge application quantities is explored. Implementation of the EPA regulations would severely limit the land application of Cd sludge in the Metropolitan Sanitary District of Greater Chicago under its current land application programs. A comprehensive industrial waste survey was conducted to determine the present industrial discharges of Cd in the district's service area. Only 37.8% of the Cd loading to the treatment plants was from industrial sources. The remaining 62.2% was from nonindustrial sources over which the district has no legal control. Reducing the industrial waste Cd standard from 2.0 mg/l to 0.5 mg/l would have only a minimal effect on the Cd loadings. There has already been a 57.7% reduction in influent Cd loadings since 1971 as a result of strict enforcement of the district's Industrial Waste Ordinance. (Geiger-FRC)

POTENTIAL USE OF EARTHWORMS AS A SOLUTION TO SLUDGE MANAGEMENT,
State Univ. of New York Coll. of Environmental Science and Forestry, Syracuse.
R. Hartenstein.
Water Pollution Control, Vol 80, No 5, p 638-643, 1981. 1 Fig, 15 Ref.

Descriptors: *Activated sludge, *Sludge disposal, Sludge digestion, Composting, Earthworms.

Activated sludge, which ordinarily dries as a form with relatively small surface area, has a high potential for putrescence, pathogenicity, and toxicity. A procedure for using a microbivorous earthworm, Eisenia foetida, to convert activated sludge into castings, which have a relatively large surface area and low potential for putrescence, is described. This procedure requires two unit operations: the production of a stock of earthworms (vermiculture) and the use of the stock for conversion of sludge to castings (sludge vermicomposting). An initial supply of E. foetida may be obtained from biological filter beds in many sewage treatment facilities. Vermiculture then involves cultivation of these earthworms in horse manure uncontaminated by urine and harvesting with an inclined rotating drum on a monthly basis. Experimental studies have indicated that anaerobic sludges are not amenable to digestion by E. foetida. One volume of earthworms is placed into 20 volumes of activated sludge containing 12 to 15% or more solids in a layer not exceeding about 30 millimeters. The earthworms appear to convert all the sludge into castings within 10 days at 20 to 25 C. After the solids content is allowed to increase to about 20 or 25%, the worms can be harvested for reuse. Only small losses in earthworm numbers occur in the vermicomposting process. It is suggested that the application of vermiculture to sludge management may provide a reliable, economical, and environmentally beneficial resolution to sludge management problems. (Carroll-FRC)

WASTEWATER MANAGEMENT IN COASTAL NORTH CAROLINA,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences.
R. J. Nierstedt, D. A. Okun, C. R. O'Melia, J. K. Sherwani, and M. S. Heath.
Report No. 165, December, 1980. Water Resources Research Institute, North Carolina State University, Raleigh. 208 p, 13 Fig, 50 Tab, 14 Maps, 77 Ref.

Descriptors: *Wastewater treatment, *Wastewater outfall, *Wastewater management, *Coastal waters, *Ocean dumping, Inland waterways, Chlorination, Secodary wastewater, Shellfish, Ecological effects, Aquatic environment, Water circulation, Outfall sewers, Dare County, *North Carolina.

Rapid growth and development in North Carolina have done serious damage to the aquatic environment. The purpose of this study was to evaluate the options for water management in coastal North Carolina, and focused on Dare County in the north and Carteret County in the southern area. Three wastewater management options were examined, with treatment appropriate to the method of disposal; 1) discharge to inland coastal waters; 2) discharge to the ocean; and 3) disposal on land. Options 2 and 3 are the most feasible. Inland coastal waters have poor circulation and the shellfish growing areas are extremely vulnerable to pollution. Ocean disposal is the most environmentally acceptable; however, extensive sewerage is needed to collect the wastewater at a single point for disposal. Four options for ocean disposal are evaluated; primary treatment, with and without chlorination; and secondary treatment, with and without chlorination. The least cost option that provides adequate beach protection in both areas is primary treatment plus chlorination. Ocean outfalls are only economical if they serve large populations, so this study includes an assessment of institutional options available for implementing regional wastewater collection and disposal systems. Primary responsibility would be placed on county governments. The main legal issue to be resolved is authorized for ocean outfalls in North Carolina in the first place and federal constraints on ocean discharge with only primary treatment. (Atkins-Omniplan)

HUMIC SUBSTANCES IN SEWAGE SLUDGES,
Catania Univ. (Italy). Inst. of Agricultural Chemistry.
R. Riffaldi, F. Sartori, and R. Levi-Minzi.
Environmental Pollution, Series B, Vol 3, No 2, p 139-146, February, 1982. 1 Fig, 3 Tab, 25 Ref.

Descriptors: .

The purpose of this research was to make a detailed investigation of the humic compounds of municipal sewage sludges in the form in which they are usually applied to agricultural land. Sewage sludges were collected from ten plants located in Tuscany and receiving wastewater mainly from domestic districts. Two samples were anaerobically digested, while all the other sludges were subjected to aerobic digestion. The results indicate that the content and distribution of humic substances in sewage sludges vary widely, probably depending on the collateral industrial activities in the sewage collection area. No correlation has been sought between differences in the sludges and type of digestion owing to the limited number of plants considered, particularly of those characterized by anaerobic digestion. Sludge humic acids and fulvic acids appeared to be more aromatic and/or constituted by smaller size particles than soil humic acids and fulvic acids. They appear to be classed as a young form of humic substance. It was concluded that although humic carbon in the sludges represents only about 17% of total organic carbon, increasing amounts of these materials applied to agricultural land can effectively supply to the soil a considerable amount of the most chemically and physically active organic matter. (Baker-FRC)

CHANGES TO A SOIL ON IRRIGATION WITH A SANITARY LANDFILL LEACHATE,
State Pollution Control Commissions, Lidcombe (Australia).
K. Y. Chan.
Water, Air, and Soil Pollution, Vol 17, No 3, p 295-304, 1982. 4 Fig, 5 Tab, 7 Ref.

Descriptors: *Leachates, *Soil porosity, *Wastewater irrigation, Waste disposal, Waste characteristics, Landfills, Sanitary landfills, Water pollution effects, Irrigation, Ion exchange, Wastewater disposal, Calcium, Magnesium, Soil disposal fields.

Sanitary landfill leachate (pH 10.3 and COD, 1240 ppm) was applied to soil columns containing soil covering samples from a landfill site in Australia. In the month-long expeeriment 370 cm of the leachate was applied to the 40.6 cm long, 9.53 cm diameter soil columns. Soil pH changed from 5 to 10 during the irrigation. The Mg-dominated soil changed to an exchangeable Ca-dominated soil. Mg was displaced by ion exchange at acid pH, but at pH 10, 14.2 meq Mg per 100 g (3 times the cation exchange capacity of Mg) was adsorbed in non-exchangeable forms at the immediate surface of the soil column by specific adsorption reactions. Distilled water applied to leachate-treated soil columns in a simulation of rainfall reduced hydraulic conductivity by 64-fold. This was caused by clay dispersion and reduction in pore space. To avoid death of vegetation and reduction in adsorption efficiency of the soil receiving the leachate, the leachate and soil must first be fully characterized. Then the wastes must be modified by pretreatment, such as dilution, to minimize adverse effects. (Cassar-FRC)

DYNAMIC PARAMETER TUNING FOR WATER DISTRIBUTION NETWORK MODELS IN AN EXTENDED PERIOD SIMULATION,
Sheffield Univ. (England). Dept. of Control Engineering.
C. M. Rahal, and M. J. H. Sterling.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 1, p 151-164, March, 1981. 2 Fig, 7 Tab, 10 Ref.

Descriptors: *Networks, *Water distribution, *Model studies, Simulation analysis, Water supply systems, *Yorkshire Water Authority, Reservoirs, Algorithms, England.

A dynamic parameter tuning algorithm was developed so that results of simulating water distribution systems agreed with actual network operating and calibration data. This algorithm extends the static parameter algorithm so that both may be used for network validation. The dynamic parameter tuning algorithm selects the loads that have the highest sensitivity coefficients for any particular discrepancy and only chooses loads that are applied to the load nodes for which measurements are available. The model handles variations in time and reservoir dynamics. The network model is solved at every time interval and information derived from the balanced model is used to detect the parameters which should be tuned in order to force agreement between simulated and observed data. Aqua, No 4, p 86-89, April, 1980. 2 Fig, 2 Tab, 8 Ref.

Descriptors: *Water treatment, *Biological treatment, *Filtration, Fluidized beds, *Pretreatment of water, Chemical coagulation, Ammonium, Nitrogen compounds, Organic matter, Organic carbon, Halomethanes, Chlorination, Drinking water, Biological filters, Activated sludge treatment.

Improved purification of water prior to disinfection would reduce the need for disinfectant addition with resultant formation of undesirable compounds such as halomethanes. Biological filtration is a promising pretreatment method, but has suffered from the disadvantages of slow filtration speed and large filter areas. The use of fluidized bed techniques could alleviate these problems. Two pilot plants were set up, one with a single fluidized bed and another with a double oxygenated fluidized bed, for rapid biological filtration of Marne river water. After ten days of maturation the following percent reductions of raw water constituents were achieved: ammonium nitrogen: single bed 22%, double bed 57%; nitrite and nitrate nitrogen: single bed no change, double bed increase; oxidizability, basic: single bed 32%, double bed 19%; oxidizability, acidic: single bed 35%, double bed 28%, taste threshold: single bed 8%, double bed 9%; T.O.C.: single bed 32%, double bed 28%; and halomethane precursors: single bed 30%, double bed 39%. Further water quality improvements could be obtained by subsequent rapid filtration through a 120 cm sand layer at 6 cu m per sq m per hr (ammonium elimination was virtually complete), while slow filtration through adsorbent materials further reduced organic matter content. CENTRALIZED CONTROL OF THE WATER SUPPLY COMPLEX FOR THE MARSEILLES URBAN AREA (CONTROLE CENTRALISE DU COMPLEXE D'ALIMENTATION EN EAU DE L'AGGLOMERATION DE MARSEILLE),
Societe des Eaux de Marseille (France). Dept. Adduction et Exploitation.
J. F. Garcin.
Aqua, No 5, p 8, May, 1980. (English summary).

Descriptors: *Water distribution, *Remote control, *Computers, Automation, Sluice gates, *Marseilles, *France, Water treatment, Water quality.

The Marseilles Water Company has introduced a remote control system for its production supply and distribution installations, including the Marseilles Canal, four water treatment stations, and a 2060 km distribution network. The system is based on question-response type transmission equipment using radio transmission, a main and a secondary control center, and 120 stations. The system performs remote signaling, measurement, alarm and instruction functions. It provides data on the positions of the sluice gates in the Canal, pump functioning, water level at different points in the canal, pressures or reservoir levels in the distribution network, and water quality parameters. Two operators are always on duty at the control center. The operators may make use of two system maps, a battery of recorders, and printer, a terminal screen for visualizing various stations, and a control keyboard. Routine and special data are provided, and

commands are initiated from the center. Service to subscribers has been improved by this system. (Carroll-FRC)

ELECTROPHORETIC MOBILITY MEASUREMENTS IN COAGULATION WITH ALUMINUM SALTS,
Syracuse Univ., NY. Dept. of Civil Engineering.
R. D. Letterman, S. G. Vanderbrook, and P. Sricharoenchaitkit.
Journal of the American Water Works Association, Vol 74, No 1, p 44-51, January, 1981. 11 Fig, 1 Tab, 22 Ref.

Descriptors: *Chemical coagulation, *Electrical properties, *Process control, *Aluminum compounds, Silica, Particulate matter, Kaolin, *Alum, Flocculation, Laboratory studies, Hydrogen ion concentration, Colloids, Suspended solids, Separation techniques, *Water treatment.

Studies were made to improve the usefulness of EM (electrophoretic mobility) as a control technique in alum coagulation. Effects of aluminum, salt and initial suspension concentrations and pH were assessed on flocculation efficiencies of particles in batch experiments then the results obtained were comnpared with corresponding electrophoretic mobilities of the particles. At low sulfate concentrations, efficient flocculation was limited to a range of aluminum concentrations that bracket the concentration corresponding to EM = 0. At increasing sulfate concentrations, flocculation increased indefinitely as the aluminum concentration increased. The critical anion (nitrate or sulfate) concentration was negligible at pH values of 3.5-4.5 and above 7.5. At low sulfate concentrations the range of aluminum concentrations which corresponded to flocculent suspensions widened and shifted toward higher aluminum concentrations as the kaolin concentration increased from 50 to 500 mg/1. The aluminum concentration corresponding to zero electrophoretic mobility is essentially directly proportional to the kaolin concentrations. Some evidence was seen that the approximate critical EM value is independent of the type of anion and the particular destabilizing combination of pH and anion concentration. The range of EM values that corresponds to flocculent suspensions seems to depend to some extent on the type of article used in the suspension (silica or kaolin). Results of the study support the contention that hydrolyzed aluminum adsorbs on the particles and forms a coating of aluminum hydroxide precipitate. Addition of aluminum sulfate to a suspension with negligible concentrations of destablizing electrolytes and pH < 7.5 can lead to two regions of flocculation -- a low aluminum flocculation zone corresponding to the destabilization of the positive precipitate coated particles. FACTORS AFFECTING COLIFORM BACTERIA GROWTH IN DISTRIBUTION SYSTEMS,
Victoria General Hospital, Halifax (Nova Scotia). Div. of Laboratories.
R. S. Martin, W. H. Gates, R. S. Tobin, D. Grantham, and R. Sumarah.
Journal of the American Water works Association, Vol 74, No 1, p 34-37, January, 1982. 4 Fig, 2 Tab, 25 Ref.

Descriptors: *Coliforms, *Water treatment, *Lime, Hydrogen ion concentration, Water distribution, *Halifac, *Nova Scotia, Corrosion, Water quality, Deterioration, chlorination, Pipes, Klebsiella, Bacterial analysis, Lake Pockwock.

A new surface water source, Lake Pockwock, and treatment plant were put into service in Halifax, Nova Scotia, in the summer of 1977. During the summer and fall months up to 30% of the distribution samples showed the presence of coliform bacteria, mainly Klebsiella and other enterobacteria. Postfiltration lime addition at the treatment plant appeared to alleviate the coliform problem. The effects of pH change and lime addition on Klebsiella pneumoniae isolated from the distribution system were investigated in the laboratory. Minimum survival times were found at pH 9.0 and maximum survival times at pH 7.3. Addition of more than 5 mg/liter of lime to raw water caused at least 99% reduction in K. pneumoniae levels. Tubercle material scraped from a pipe removed from the distribution system sustained bacterial growth and reduced a free chlorine residual of 2.5 mg/liter to low levels within 8-14 hr. The strong pH modification and lethal effect on bacteria resulting from lime addition were moderated by the addition of 10 g/liter tubercle material. Lime addition was more effective in controlling the growth of coliform bacteria than increasing the chlorine residual. (Carroll-FRC)

LABORATORY TESTING OF OZONATION SYSTEMS PRIOR TO PILOT-PLANT OPERATIONS,
Vassar Coll., Poughkeepsie, NY.
P. C. Chrostowski, A. M. Dietrich, and I. H. Suffet.
Journal of the American Water Works Association, Vol 74, No 1, p 38-43, 1982. 7 Fig, 5 Table, 34 Ref.

Descriptors: *Ozone, *Water treatment, *Drinking water, Experimental design, *Ozonation, Organic compounds, Oxidation, Biological treatment, Activated carbon, Chemical analysis.

An experimental protocol was designed for bench-scale testing of an ozonation system prior to pilot-plant or full-scale operation. The protocol, a rationalized approach to determination of the chief system parameters, was applied to the ozone pretreatment stage of a biological activated carbon (BAC) process. The need for treatment prior to ozonation was assessed; it was found that the goal of organics removal is best achieved by placing the ozone unit immediately after raw water intake. Comparison of several techniques for quantifying organics removal resulted in selection of an automated system for monitoring UV-absorbing substances at 254 nm. The rates of the ozone-organics and ozone decomposition reactions were determined and used to calculate contact time, contractor volume, optimum alkalinity, and other system parameters. Finally experiments aimed at optimizing the applied ozone dose were conducted. The protocol facilitates system design and is being improved to permit optimization of ozone systems as well as pediction of the effects of ozone in a given system on an individual water supply. COMPARISON OF TRIHALOMETHANE LEVELS AND OTHER WATER QUALITY PARAMETERS FOR THREE TREATMENT PLANTS ON THE OTTAWA RIVER,
Health and Welfare Canada, Ottawa (Ontario); and Environmental Health Directorate, Ottawa (Ontario).
R. Otson, D. T. Williams, P. D. Bothwell, and T. K. Quon.
Environmental Science and Technology, Vol 15, No 9, p 1075-1080, September, 1981. 1 Fig, 3 Tab, 24 Ref.

Descriptors: *Halogens, *Methane, *Water quality, Chlorinzation, Potable water, Water treatment, Seasonal variation, Canada, *Ottawa River, Water treatment facilities, Potable water.

A detailed, 13-month study of water quality in three potable water treatment systems obtaining raw water from the Ottawa River in Canada was conducted to complement earlier studies of water quality parameters and treatment practices and studies of factors controlling the production of trihalomethanes (THMs) in potable water treatment systems. Treated water from two plants, which are of similar design and applied conventional coagulation and sedimentation with rapid sand and anthracite filtration, was similar, but differed significantly from treated water from the third treatment plant, which had a different design and used different chlorination practices. Pearson correlation coefficients showed a complex relationship among several water quality parameters. Multiple regression analysis showed that chlorine dosages and demands were the dominant factors controlling chloroform levels, while other parameters displayed minor effects which varied from system to system and according to stage of treatment. Temperature, chlorine dosages and demands, THM levels, alkalinity measurements, and alum dosages all showed pronounced seasonal variation. THM levels varied significantly over a 24-hour period at any particular point in a system. (Carroll-FRC)

FACTORS INFLUENCING FORMATION OF TRIHALOMETHANES IN DRINKING WATER WITH SPECIAL REFERENCE TO SWEDISH CONDITIONS,
National Inst. of Environmental Medicine, Stockholm (Sweden).
H. Norin, L. Renberg, J. Hjort, and P. O. Lundblad.
Chemosphere, Vol 10, No 11/12, p 1265-1273, November/December, 1981. 6 Fig, 3 Tab, 24 Ref.

Descriptors: *Chlorinated hydrocarbons, *Disinfection, *Chlorine, *Trihalomethanes, Organic compounds, Drinking water, *Sweden, Chlorine dioxide, Ammonium sulfate, *Water treatment, Water quality control.

Trihalomethane (THM) formation during water treatment with chlorine and ammonium sulfate was studied in full-scale experiments at the Norsborg water works, Stockholm, Sweden. Under normal conditions (0.5 mg per liter C1 and 0.15 mg per liter ammonium sulfate) total THM concentrations increased from 1.8 to 4.1 micrograms per liter within 2 hours. This indicated that drinking water at the tap had a higher THM concentration than water leaving the treatment plant. THM levels decreased with increases in ammonium sulfate doses: 5.1 and 1.7 micrograms per liter THM at ammonium sulfate doses of 0 and 0.35 mg per liter, respectively. THM concentrations decreased with increases in ammonium sulfate/chlorine ratio: 5.1 to 0.9 micrograms per liter THM at ratios of 0 and 1.1, respectively. A high dose of C1 (2 mg per liter) without ammonium sulfate addition produced 70 microgams per liter THM after a 6 day laboratory experiment. Additional laboratory experiments using 2 mg per liter chlorine dioxide produced only 1.8 micrograms per liter THM after 6 days. Sampling of community water disinfected with chlorine dioxide showed only bromodichloromethane present at levels of 0.02 micrograms per liter and no chloroform, dibromochloromethane, or bromoform. Instantaneous THM levels found in water at 191 Swedish water works using some form of disinfection were 0.2 to 200 micrograms per liter. Most of the samples had THM levels of 25 micrograms per liter or below. (Cassar-FRC)

POTABLE WATER PRODUCTION IN HOLLAND.
Water Services, Vol 85, No 1030, p 618-619, December, 1981.

Descriptors: *Drinking water, *Water treatment, *Water supply, *Netherlands, Desalination, Distillation, Surface water, Maas River, Rhine River, *Groundwater, Ground contamination, Activated carbon, Filtration, Dune infiltration.

Annual water production in the Netherlands is approaching the two billion cubic meter mark, yet the provision of water with suitable quality is becoming increasingly difficult. Pollution is threatening Holland's groundwater, which supplies two thirds of the drinking water. Two national organizations are concerned with water recovery and production research. Much research is being conducted in hydrogeology to secure groundwater

USDA U. of I. URBANA-CHAMPAIGN

supply. Activated carbon is being used for groundwater purification at some points where chemicals have penetrated through the subsoil into the groundwater. In coastal areas, natural groundwater is too salty for use, except in the case of the coastal dunes. Reservoirs have been constructed on the Maas river, which is less polluted than the Rhine, to equalize the annual flow. Reservoirs have been lined with nylon mats and bitumen, but algae control is still required. Plate clarifiers are widely used for initial purification, followed by sand filtration, carbon filtration if necessary (carbon is obtained from peat in some areas), and chlorination or ozonization for disinfection. Electrochemical and physical purification methods are under investigation. A seawater distillation plant has been constructed on the island of Texel; studies in the Netherlands Antilles have shown that solar distillation plants are feasible. (Carroll-FRC)

NEW TELEMETRY SYSTEM FOR THE CAMBRIDGE WATER COMPANY.
Water Services, Vol 85, No 1030, p 606-609, December, 1981.

Descriptors: *Water supply, *Automation, *Telemetry, *Cambridge Water Company, *England, Computers, Water management, Water quality management.

A complete telemetry control system was installed by the Cambridge Water Company in 1980. The hardware uses standard modules, with communication by UHF radio to 31 outstations and substations. At two minute intervals the system scans the network points, looking for changes of status or exceeding of preset values. In case of abnormal reports, the operator may institute a control function. Values are indicated in user selected units or by color changes. All aspects of system operation are assigned security levels. Only selected records are stored for historical use: data on flow rates in various areas of the network and patterns in daily water supplies. The flexibility of the system allows for expansion and modification. (Carroll-FRC)

THE HYGIENIC CONTROL OF SWIMMING BATHS.
Water Services, Vol 85, No 1030, p 595-597, December, 1981. 2 Fig, 1 Tab.

Descriptors: *Water treatment, *Swimming pools, *Disinfection, Chlorine, Chlorine dioxide, Ozone, Isocyanurates, Filtration, Flocculation, Water circulation, Hydrogen ion concentration.

Water treatment systems employed for maintaining the safety of swimming pool water include flocculation, disinfection, algal destruction and filtration operations. A balance between contaminants introduced and removed must be maintained by fresh water addition and uniform circulation of the water by pumping. The circulation system is generally aimed at circulating the pool contents every 8-10 hr; an average of 2 cu m of treated water should be available for each swimmer. At least 30 liters of fresh water per bather per day should be added to reduce salt accumulation. The addition may be made every 2-3 days when the filters are backwashed. Flocculants are generally aluminum or iron compounds, with the former being more sensitive to pH of the water. Filtration removes both the flocs produced by the flocculants and other small-particulate materials. Disinfection should destroy 99.9% of bacteria present in 30 sec, which can be accomplished by maintaining a redox potential of 700 mV. Sodium hypochlorite solution is the most commonly used disinfectant, but chlorine dioxide, ozone and isocyanurate have also been used. Ozone must be removed by activated carbon filtration after disinfection of the water. Isocyanurates are suitable as simple methods of treatment for small pools. (Carroll-FRC)

DESIGN, CONSTRUCTION AND OPERATION OF A NEW FILTER APPROACH FOR TREATMENT OF SURFACE WATERS IN SOUTHEAST ASIA,
SEATEC International, Bangkok (Thailand).
R. J. Frankel.
Journal of Hydrology, Vol 51, No 1-4, p 319-328, May, 1981. 4 Fig, 2 Tab, 4 Ref.

Descriptors: *Water treatment, *Filtration, *Surface water, Gravity filters, Carbon filters, Potable water, Wastewater treatment, Adsorption, Design criteria, *Southeast Asia, Philippines, Thailand.

The development of simple, inexpensive, and efficient water purification and wastewater treatment methods suitable for use in rural communities in Southeast Asia is reported. The filter utilizes local materials that are widely available, principally shredded coconut fiber and burnt rice hulks, in a two-stage filtering process designed as a gravity-fed system. Since the materials are inexpensive enough to discard after use, backwashing is eliminated. Raw water is first passed through shredded coconut fiber for an initial reduction in turbidity and suspended solids removal. This step provides a substitute for the coagulation and sedimenation phases of conventional water treatment plants. The treated water is then passed through the burnt rice husks, removing residual turbidity and bacteria in a manner similar to that accomplished by slow sand filtration in traditional systems, with the additional benefits of taste, color, and odor removal through the absorption properties of the activated carbon in the husks. This system generally does not require the addition of any chemicals. Use of the two filters in series generally produces a clear effluent which is free of odor and color and is of an agreeable and acceptable taste to the villagers. Bacterial removals average between 60 to 90 percent without the use of any disinfectant. Experiences with eight village size units ranging in capacity from 1.0 to 15.0 cubic meters per hour which were constructed in Lower Mekong River Basin countries and in the Philippines are described. PRELIMINARY SCREENING OF BACTERIAL COMPONENTS AS ORGANIC PRECURSORS TO THE FORMATION OF TRIHALOMETHANES,
Missouri Water Resources Research Center, Columbia.
R. B. Jacquez, and F. Dolan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220633, Price codes: A05 in paper copy, A01 in microfiche. Report, July 31, 1981, 76 p, 12 Fig, 8 Tab, 31 Ref. OWRT A-116-MO(1). 14-34-0001-0127.

Descriptors: *Trihalomethanes, Organic precursors, *Bacteria, *Drinking water, Chloroform, *Chlorination, Iron, *Water treatment, Water pollution sources.

The bacteria from a suspended growth system were studied as organic precursors to the formation of THM's. THM production was monitored as a function of initial chlorine dose and the concentration of bacterial mass as measured by turbidity. Tests were conducted on a batch basis. Ferric iron was also examined for its potential to act as a catalyst for THM production during the chlorination of bacterial cells. In a system saturated with chlorine, chloroform formation was found to increase linearly with the amount of cell mass used as an organic precursor. Chloroform production was also found to increase in relation to a greater exposure of cell surface area (e.g. dispersed cells vs. flocculated cells). Ferric iron appeared to catalyze chlorination reactions in water, causing increased chlorine consumption, but did not increase THM production.

Descriptors: *Chlorine dioxide, *Toxicity, *Water treatment, *Disinfection, Metabolites, Chlorination, chlorite, chlorate, Chloramine.

Chlorine dioxide has been identified as a potential water disinfectant alternative to chlorination. A three-phase human investigation was undertaken to assess the safety of chlorine dioxide and its metabolites. In phase I, normal healthy adult males were treated with successive increasing doses of chlorine dioxide, chlorite, chlorate, chloramine, chlorine or untreated water. Phase II considered the effect on normal subjects of daily ingestion of disinfectants at a concentrations of 5 mg/L over a 12 week period. In phase III, chlorite, at a concentration of 5 mg/L was administered daily to three glucose-6-phosphate dehydrogenase (G-6-PD) deficient subjects. Physiological impace was assessed by evaluation of a large battery of qualitative and quantitative tests. All three phases of this clinical evaluation were completed uneventfully. there were no obvious undesirable clinical sequellae noted by any of the participating subjects or the observing medical team. In several cases statistically significant trends in certain biochemical or physiological parameters were associated with treatment; however, none of these trends were judged to have physiological consequences. Within the limits of the study, the relative safety of oral ingestion of chlorine dioxide and its metabolites, chlorite and chlorate, was demonstrated. (Moore-SRC)

WATER SYSTEM DESIGN MEETS MODERN CHALLENGES,
Watson and Co., Tampa, FL.
J. L. Carter.
Water/Engineering and Management, Vol 128, No 12, p 33-34, December, 1981. 3 Fig.

Descriptors: *Water supply, *Water quantity, *Water treatment, *Wells, Recreation facilities, Recreation, Filtration, *Drinking water, Water storage, Groundwater recharge, Rainfall, *Tampa, Florida, Water supply systems, Design criteria.

The selection and design of a supplementary drinking water system in Tampa, Florida is described. Three issues were of prime consideration in this undertaking: (1) achieving a yield of 40 million gallons per day, (2) minimizing ecological impact, and (3) conserving energy. This task was further complicated by the fact that the water regime in this area of Florida is highly variable. A recharge area was chosen as the well field. Service road construction was designed to minimize the effect on the natural surroundings, and wells are scattered through the well field, equipped with dual purpose pump houses, which also serve as picnic shelters that blend into the surroundings. Energy conservation is achieved in that gravity is used to move water through the processing facility. (Titus-FRC)

THE USE OF ACTIVATED CARBON IN WATER TREATMENT,
Anglian Water Authority (England).
C. R. Hayes, and C. J. Whitford.
Effluent and Water Treatment Journal, Vol 22, No 1, p 9-16, January, 1982. 3 Fig, 5 Tab, 10 Ref.

Descriptors: *Activated carbon, *Organic compounds, *Drinking water, *Water treatment, Trihalomethanes, Filtration, Adsorption, Trace levels, Performance evaluation, Taste, Odor control, Economic aspects, Ozone, Oxidation.

Experience of the Anglian Water Authority in use of powdered activated carbon (PAC) and granular activated carbon (GAC) in water treatment is reviewed. Although GAC is more effective than PAC in removing tastes and odors, it is presently being used in only four water works in the United Kingdom, whereas PAC is used in 100 works. GAC removes organic contaminants, but the more volatile compounds are removed effectively only during early bed life. Organochlorine pesticides and other high molecular weight low polar compounds are more effectively adsorbed. If more than 60% of total organic carbon in the range of 4-7 mg per liter must be removed from surface water, GAC is relatively expensive. Ozone pretreatment improves GAC performance, but temperature and other oxidants have little effect. The most attractive option with respect to capital costs is using GAC to replace sand at the rapid gravity filtration stage. The use of GAC is expected to increase with the public concern about trace organic contaminants in drinking water. It is not likely that PAC use will increase. (Cassar-FRC)

SAVING ENERGY BY CATALYTIC REDUCTION OF OXYGEN IN FEEDWATER,
Bayer A.G., Leverkusen (Germany , F.R.).
B. Martinola, and P. Thomas.
Effluent and Water Treatment Journal, Vol 21, No 12, p 542-546, December, 1981. 10 Fig, 5 Tab, 6 Ref.

Descriptors: *Oxygen, *Feedwater treatment, *Catalysts, *Dissolved oxygen, Residual oxygen, *Industrial water, Water use, Water treatment, Energy conservation.

It is virtually always necessary to remove most of the dissolved oxygen from water for steam generating stations, industrial process waters, and heating water in order to avoid corrosion of equipment in which the water is circulating. The most common method used to reduce dissolved oxygen, thermal degassing under vacuum or at slightly increased pressure, is generally inefficient and energy-expensive. Chemical methods, including reduction with sulfite and hydrazine, result in unwanted by-products and are often expensive. The use of hydrogen gas introduced into the water to react with the dissolved oxygen to produce water is a simple process which is also energy-saving. However, the reaction must be accelerated catalytically at low temperatures in order to be completely terminated in a sufficiently short time. Tests were conducted to design a simple reaction unit, to identify a good catalyst, and to determine the optimum operating conditions. Pilot plant tests were conducted to examine design and operating options. Metallic palladium was selected as the catalyst. Ion exchange resins were doped with various amounts of palladium and placed in columns through which water was passed. The size of the individual beads ranged from 0.3 to 1.5 millimeters. An industrial-scale unit for the production of 450 cubic meters per hour of oxygen-free water was constructed. After stoichiometric addition of hydrogen, residual oxygen values of about 20 parts per billion were obtained with a residence time of 30 seconds. There were no signs of fatigue in the catalysis resin after treatment of over 450,000 bed volumes of water. The required apparatus is simple and requires almost no maintenance. The use of this system is recommended wherever the heat used for thermal degassing cannot be recovered. (Carroll-FRC)

BIOLOGICAL DENITRIFICATION FOR POTABLE WATER TREATMENT,
R. Gauntlett, and T. F. Zabel.
Water Services, Vol 86, No 1031, p 17-18, January, 1982. 3 Fig, 1 Tab, 8 Ref.

Descriptors: *Denitrification, *Sand filters, *Nitrates, *Water treatment, Fluidized beds, Biological treatment, Filters.

Seasonal high nitrate levels in British rivers and groundwaters used for drinking water supplies prompted investigations of methods of biological denitrification. A fluidized sand bed removed up to 10 mg per liter nitrates with a bed depth of 4-5 m, temperatures as low as 2 C, and an upflow rate of 20 m per hour. Methanol was an effective source of carbon for the denitrifying bacteria; acetic acid produced excessive slime and occasional high nitrate levels in treated water. Sand cleaning and aeratin were necessay parts of the fluidized bed process. The expanded sand bed, an alternative to the fluidized bed, removed 10 mg per liter N at an upflow rate of 14 m per hour, temperatures of 3-5 C, and bed depth of 1.5 m. Backwashing removed excess bacterial growth. Raw water turbidity of > 30 FTU adversely affected performance. The 10-14 day start-up period of the denitrigying process requires anticipation of the high seasonal nitrate levels. (Cassar-FRC)

EXTENDED DECHLORINATION STUDIES WITH GRANULAR ACTIVATED CARBON FILTERS,
Georgia Inst. of Tech., Atlanta. School of Civil Engineering.
M. T. Suidan, W. H. Cross, and K. A. Chacey.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2634-2646, November, 1980. 14 Fig, 1 Tab, 15 Ref.

Descriptors: *Carbon filters, *Oxidation, *Mathematical models, *Activated carbon, *Residual chlorine, Chlorine, Halogens, *Separation techniques, Water treatment, Wastewater treatment, Disinfection.

When activated carbon which is used to control residual chlorine levels is oxidized by free chlorine, a dark brown color results that renders the product water useless for consumption. An operating procedure has been developed which allows for the removal of column segments that have reached predetermined oxidation levels while permitting a more efficient use of activated carbon. A mathematical model was developed which describes the decreasing bed-length dechlorinator and can simulate the stratified-carbon column in both upflow and downflow operating modes. The model was tested over a wide range of operating and environmental conditions. The extent of carbon utilization prior to elimination and the operating pH had a marked effect on the performance of the system. Bed length had a significant influence on the service life of a carbon dechlorination column. Increased detention of flow resulted in increased carbon utilization efficiency. Higher temperatures also improved performance and extended the service life of a column. Mode-of-flow studies showed that the upflow mode would result in an extended service life of the contactor while allowing for more uniform exhaustion of the carbon along the column. Efforts to use one representative carbon size throughout the column failed due to a redistribution of particle sizes in a stratified bed during carbon removal. (Geiger-FRC)

METHANE IN WATER WELLS,
Michigan Dept. of Public Health, Lansing.
D. K. Keech, and M. S. Gaber.
Water Well Journal, Vol 36, No 2, p 33-36, 1982. 5 Fig, 1 Tab.

Descriptors: *Methane, *Water quality, *Water treatment, Hydrocarbons, Wells, Potable water, Separation techniques, *Water wells, Gases, *Ventilation.

A treatment is described whereby methane and other dissolved gases in water wells can be effectively removed. Proper venting at the well head is essential to allow the methane to be removed from the well. The upward movement of water in the casing when the well is recovering after pumping will push the accumulated methane gas out the top of the well. If large amounts of combustible gases are present, the well vent should terminate above a person's head to avoid ignition by lawnmowers, barbeque grills or other items. The installation of a gas shroud on the submersible pump has been successful in several gaseous water wells. An additional method involves the use of a vented storage tank with a spray bar mechanism. The spray bar is a length of pipe with small holes drilled in it to disperse the water. Agricultural spray nozzles may be used for this purpose. Another method involves the use of an air release valve on a galvanized storage tank. An air-separator system was installed in a newly constructed high school in northern Michigan to solve the gas in water problem there. The air separator is a cylindrical device with an inlet near the top, outlet near the bottom and air vent on top. Water flowing through the unit creates a centrifugal force which causes heavier, gas-free water to move toward the outside. Lighter gas-entrained water moves toward the center due to a low velocity vortex being created within the air separator. Gas rises and exits through a vent line into the top of a vented tank. A vent from the tank terminates about a foot above the roof line of the building. (Baker-FRC)

DEVELOPMENT OF EVALUATION OF ION-EXCHANGE RESINS FOR REMOVAL OF SPECIFIC METALS IN WATER TREATMENT,
West Virginia Univ. Morgantown. Water Research Inst.
A. Winston, C. R. Jenkins, W. Lerdthusnee, and S. J. Masten.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224593, Price codes: A03 in paper copy, A01 in microfiche. Information Report 17, 1981. 22 p, 6 Fig, 2 Tab, 7 Ref. OWRT A-043-WVA(1), 14-34-0001-1152.

Descriptors: Acid mine water, Cation exchange, Chelation, *Demineralization, *Ion exchange, *Iron, *Polymers, *Water treatment, Groundwater, Heavy metals, Industrial wastes, Manganese, Mine water, Treatment, *Wastewater treatment, Water pollution, Water supply.

An ion-exchange resin specific for iron was developed and evaluated for its performance in removing iron from water supplies. The resin was synthesized by converting the carboxyl groups of Chelex 100 (Bio-Rad) to hydroxamic acids by reaction with ethylchloroformate followed by hydroxylamine. The resin was evaluated in bench scale equipment consisting of a column 5 cm in diameter by 1.0 m containing from 0.5 to 1 pound of resin. Iron (III) perchlorate solutions were passed through the column and the iron concentration of the effluent was monitored by atomic absorption spectroscopy. Breakthrough was considered to have occurred when the effluent iron concentration had reached 0.3 ppm. The effects of flow rate and iron concentration on column performance were determined. Increasing flow rate and increasing iron concentration caused decreases in operating exchange capacity of the resin. The exchange capacity varied between 2.9 and 5.8 eq iron per cubic foot of resin depending upon the flow rate and influent iron concentration. The resin can be regenerated by reduction of the iron (III) to iron (II) using sodium hydrosulfite followed by washing.

UNIV. OF ILLINOIS-CHICAGO

Aqua, No 1, p 368-376, 1982. 8 Fig, 10 Ref. English summary.

Descriptors: *Water softening, *Automation, *Control systems, *Water treatment, Paris, France, Water supply, *Seine River, Municipal water.

Examples of automation in two water treatment plants in France are described. The Morsang-sur-Seine plant (150,000 cu m per day) treats water by clarification, sand filtration, ozonation, filtration through granular activated carbon, pH adjustment, and final chlorination. A central computer coordinates all aspects of the system, monitoring water quality parameters at all stages of treatment, operating pumping equipment, regulating flow, dosing chemicals, measuring residual disinfectant, adjusting pH, designating the time for backwash, etc. The Villeneuve-la-Garenne softening plant removes carbonate from 40,000 cu m per day of water. The treatment sequence in this plant is iron removal, nitrification, sand filtration, carbonate removal, dual-media filtration, ozonation, pH correction, and final chlorination. The plant is controlled by a programmable automatic system, regulating circuits according to results of automatic monitoring of water quality and residuals. (Cassar-FRC)

DEVELOPMENT OF WATER TREATMENT IN FRANCE (EVOLUTION DANS LE TRAITEMENT DES EAUX EN FRANCE: QUELQUES EXEMPLES D'ACTUALITE),
M. Rapinat.
Aqua, No 1, p 4-9, 1982. 4 Fig, 4 Tab, 53 Ref. English summary.

Descriptors: *Disinfection, *Biological treatment, *Water treatment, *France, Chlorination, Activated carbon, Reviews, Water pollution prevention, Trihalomethanes, Ozonation, Chlorine dioxide.

The status of water treatment in France is reported. Biological processes, based on self-purification, preozonation, and activated carbon, have been developed. Chlorine dioxide and ozone have partially replaced chlorine as disinfectants; ozonation is also effective in removing organic compounds. The efficiency of sedimentation equipment has been improved. Methods to protect water supplies from accidental pollution include storage basins, rapid communications, and shutting down or emptying the treatment plant if necessary. Formation of trihalomethanes is minimized by using chlorine only at the end of the treatment process. Attention to energy conservation and decreasing chemical costs have produced rapidly responding pumping systems, systems for careful control of chemical dosages, and combination chemical-biological treatments. In the future research will center on reduction of Al concentrations, protection of aquifers from nitrate pollution, and sludge treatment. (Cassar-FRC)

TREATMENT OF WATER FROM EUTROPHIED IMPOUNDMENTS,
National Inst. for Water Research, Pretoria (South Africa).
L. R. J. van Vuuren, F. J. de Wet, and G. G. Cillie.
Aqua, No 1, p 354-360, 1982. 7 Fig, 6 Tab, 7 Ref.

Descriptors: *Flotation, *Filtration, *Eutrophication, *Water treatment, Algae, *South Africa, Dissolved air flotation, Coagulation, Pilot tests, Costs, Capital costs, Taste, Odor, Drinking water, Wastewater treatment, Water reuse.

The combined dissolved air flotation-filtration process (DAFF) was successfully applied to treatment of eutrophied surface waters in South Africa. Problems with conventional treatment of these algae-rich waters include frothing of the water, floating flocs, requirement for excessive chemical doses, very short filter runs, caking of filter sand by slime, residual turbidity in finished water, formation of a white deposit on boiling or acidification, and objectionable tastes and odors. Six eutrophied waters treated in the pilot unit included water from several rivers, a secondary municipal wastewater effluent, and a gold mine sewage works effluent. Turbidity was reduced to 0-1.5 NTU, suspended solids to 0.6-6.5 mg per liter, and chlorophyll a to 0-19 micrograms per liter. The process consisted of dosing with alum and polyelectrolyte; air flotation; and filtration through activated carbon, anthracite, and sand. Capital cost estimates for conventional (sedimentation plus filtration), flotation plus filtration (DAF), and combined flotation-filtration (DAFF) treatment were 1,977,000 1,870,000, and 1,386,000 rands (1 rand = $1.27), respectively. Unit costs of the DAFF process were 7.5% lower than for the conventional process. (Cassar-FRC)

CHEMICALS IN WATER TREATMENT--EFFECTS ON WATER QUALITY,
Water Research Centre, Stevenage (England).
T. Burke.
Aqua, No 1, p 351-353, 1982. 1 Fig, 6 Ref.

Descriptors: *Water quality, *Water treatment, *Disinfection, Chlorination, Ozonation, Activated carbon, Adsorption, Trihalomethanes, Chlorinated hydrocarbons, Denitrification, Chemical treatment, Potable water, *Chemical reactions, Adverse effects.

Most chemicals used in water treatment have some side-effects on water quality. In the conventional treatment process coagulants (alum, ferric salts, and polyelectrolytes) may enter the distribution system, producing discolored water, subsequent coagulation, difficulty in maintaining a disinfectant residual, increased corrosion, and residual Al or acrylamide monomer. Possible adverse effects of treating waters corrosive to lead pipes are calcium carbonate precipitation and breakup of deposits on the insides of pipes. Processes for removing excess nitrates include ion exchange and biological denitrification, each of which has drawbacks. The waste brine regenerant solution from the ion exchange process is costly to dispose of. In biological denitrification possible problems are sloughing of excess biological growth and residual methanol (the source of carbon). Chlorination of water produces trihalomethanes and other chlorinated compounds from the organic matter present in surface waters. Health risks of using alternative disinfectants, chlorine dioxide or ozone, have not been fully established. Activated carbon treatment, unless carefully monitored, can release harmful organics into water if the adsorbent is not regenerated before breakthrough occurs. (Cassar-FRC)

OZONE AND ACTIVATED CARBON,
C. Engels.
Aqua, No 1, p 361-367, 1982. 2 Fig, 3 Tab. English Summary.

Descriptors: *Ozonation, *Activated carbon, *Water treatment, *Dusseldorf, *Rhine River, Groundwater, Adsorption, Organic compounds, Taste, Odor control, Toxins.

The water treatment plant at Dusseldorf uses ozonation followed by activated carbon filtration to treat mixed groundwater, predominantly infiltrating through the Rhine River banks. Ozone at a concentration of about 2.5 g per cu m of water oxidizes inorganic compounds (Fe and Mn) and organic compounds (taste and odor producing substances and toxic chemicals). The oxidation products and other materials such as organic chlorine compounds are adsorbed by the activated carbon. In the final stage carbon dioxide is neutralized with NaOH. (Cassar-FRC)

WATER AND WASTEWATER TREATMENT IN LATIN AMERICA--APPLIED TECHNOLOGY,
Universidade Central de Venezuela, Caracas. Dept. of Sanitary Engineering.
G. R. Mijares.
Water Science and Technology, Vol 14, No 1/2, p 431-437, 1982. 17 Ref.

Descriptors: *Technology, *Developing countries, *Water treatment, *Wastewater treatment, *Latin America, Pathogens, Iron compounds, Filtration, Wastewater composition, Lagoons, Stabilization lagoons, Land application, Sludge drying, Disinfection.

During the last 6-7 years Latin America water and wastewater engineers have adapted sophisticated technology from industrial countries to local climates, sewage characteristics, and economic conditions. Some conditions commonly encountered in these countries are: high iron content of deep well water, a high proportion of carbohydrate to protein in wastewater, good tolerance of tropical fish to low dissolved oxygen concentrations, abundance of light energy and warm temperatures, and presence of resistant pathogens and parasites. Engineers have developed process modifications to handle these conditions. Ferrous compounds are oxidized with simple aeration towers, chlorination, or rapid turbulent mixing. High rate sedimentation apparatus made of parallel sheets of asbestos cement inclined at 45-60 degrees from the horizontal have been satisfactorily used in settling of suspended solids. Rapid filtration units operating at declining rates are smaller than conventional units. In these countries wastewater treatment and sludge digester detention times can be less because of higher ambient temperatures and less nitrogenous matter in the sewage. Settling velocity is also greater. Hydraulic and organic loads must be modified to handle specific wastewater compositions. Sewage stabilization lagoons, high-rate photosynthetic lagoons, and land applications show great promise, but the dangers posed by tropical disease organisms must be considered. Sludge drying bed area needs to be only 1/3 of beds in temperate zones. Iodine is being evaluated as a disinfection agent because schistosomiasis and amoebiasis organisms are rather resistant to destruction by chlorination. (Cassar-FRC)

EFFECTS OF SALTS ON ACTIVATED CARBON ADSORPTION OF FULVIC ACIDS,
Illinois Univ. at Urbana-Champaign. Dept. of Civil Engineering.
S. J. Randtke, and C. P. Jepsen.
Journal of the American Water Works Association, Vol 74, No 2, p 84-93, February, 1982. 19 Fig, 4 Tab, 55 Ref.

Descriptors: *Fulvic acids, *Activated carbon, Adsorption, Calcium, Magnesium, Sodium, *Salts, Water treatment, Drinking water, Potable water.

A study was conducted to more fully characterize the effects of changing concentrations of various salts on activated carbon adsorption and to consider the implications of such effects with respect to the design and operation of treatment systems for organics removal. Fulvic acids were the primary source of organic matter used, as they are considered resonably representative of naturally occurring organic substances in most water supplies. A literature review was included, which concentrated on the effects of nonreactive inorganic salts on the rate and extent of adsorption of anionic and neutral organic adsorbates onto negatively charged adsorbents. Calcium, magnesium, and sodium salts enhanced the adsorption of fulvic acids onto activated carbon. Various inorganic anions had no observable influence on the adsorption of fulvic acid. Calcium significantly influenced the adsorption of fulvic acid by a small activated carbon column. The addition of calcium greatly improved adsorption. The enhancement of fulvic acid adsorption by calcium and magnesium was less pronounced at low pH. Adsorptive capacity was most sensitive to changes in salt concentration at low concentrations of salt, with little adsorption occurring in the absence of added salts. Sodium chloride and sodium sulfate had no effect on the adsorption of fulvic acid when calcium or magnesium was present at a concentration of 0.5 mM. Adsorption

of 2,4-dihydroxybenzoic acid was influenced by salt addition in a manner similar to fulvic acids. Salts do not affect the adsorption of all organic anions in the same manner, as evidenced by the various effects of salts on the adsorption of EDTA, citric acid, and aspartic acid. (Baker-FRC)

REMOVING TRIHALOMETHANE PRECURSORS BY PERMANGANATE OXIDATION AND MANGANESE DIOXIDE ADSORPTION,
Brown and Caldwell, Walnut Creek, CA.
J. M. Colthurst, and P. C. Singer.
Journal of the American Water Works Association, Vol 74, No 2, p 78-83, February, 1982. 15 Fig, 15 Ref.

Descriptors: *Water treatment, *Drinking water, Water quality, Trihalomethanes, Manganese dioxide, Adsorption, Permanganate, Oxidation, Chloroform, Humic acids, Fulvic acids.

The effects of permanganate oxidation and manganese dioxide adsorption on the formation of trihalomethanes from humic substances were investigated. Most of the experiments were conducted with a technical-grade humic acid. Selected experimental runs were duplicated using an aquatic fulvic acid extracted from Lake Drummond, Virginia. Various concentrations of humic material were adjusted to pH 7.0 and contacted with different amounts of permanganate for 2 hours. The study demonstrated that permanganate treatment at neutral pH using doses commonly employed in water treatment practices lowers the chloroform formation potential of humic substances to some degree. The largest decreases occurred in those samples subjected to the greatest permanganate: total organic carbon concentration ratios. Similar decreases in chloroform formation potential were noted for both the humic acid and fulvic acid studied. Manganese dioxide alone did not appreciably absorb humic substances at pH 7.0. Consequently, little reduction in chloroform formation potential can be expected as a result of the presence of manganese dioxide alone. Calcium facilitated the adsorption of humic substances on manganese dioxide. Significant reductions in chloroform formation potential, TOC, and chlorine demand were noted as a result of adsorption of the humic substances on manganese dioxide in the presence of calcium. Humic acid was more easily adsorbed than the aquatic fulvic extract. (Baker-FRC)

EVALUATING REGENERATED ACTIVATED CARBON THROUGH LABORATORY AND PILOT-COLUMN STUDIES,
Philadelphia Water Dept., PA.
P. R. Cairo, J. T. Coyle, J. J. Davis, H. M. Neukrug, and I. H. Suffet.
Journal of the America Water Works Association, Vol 74, No 2, p 94-102, February, 1982. 17 Fig, 6 Tab, 16 Ref.

Descriptors: *Activated carbon, *Regeneration, Organic compounds, Carbon, Adsorption, Water treatment, Drinking water, Temperature effects.

Results are presented from ongoing laboratory and pilot-column research comparing the effectiveness of regenerated and virgin carbon for use at water treatment plants. The carbon used in the study was regenerated for one cycle at several furnace temperatures. The laboratory study showed that 542 degrees C regeneration did not restore the fundamental kinetic characteristics of virgin carbon for the test substances methyl ethyl ketone and n-butanol. For these same compounds, the 850 degree C regeneration condition produced breakthrough curves that were virtually identical to the virgin carbon. The pilot column study evaluated 542, 850 and 962 degree C conditions for F400 GAC and two gasification phase regeneration temperatures; for F300 GAC. The most significant results were shown in the breakthrough curves of chloroform for F400 operating in a postcontractor mode. The 962 degree C regenerated carbon produced an effluent concentration twice as high as the virgin, 542 and 850 degree C regenerated carbons. The total organic carbon (TOC) breakthrough curves for all virgin and regenerated F400 GACs were virtually the same. Particularly significant was the fact that the leveling-off plateau of TOC occurred for all virgin and regenerated carbons. The analysis of specific nonpolar organics by GC profiling resulted in the identification of a number of alkyl benzene compounds in the influent that were fairly effectively removed by the virgin and regenerated carbons, even after 17 weeks of operation. It is suggested that the 962 degree C regeneration may be too harsh a condition for drinking water carbon, as it was initially developed for use on carbon heavily laden with organics from industrial and municipal wastewater applications. CONSIDERING SLUDGE PRODUCTION IN THE SELECTION OF COAGULANTS,
Montgomery (James M.), Inc., Reston, VA.
C. R. James, and C. R. O'Melia.
Journal of the American Water Works Association, Vol 74, No 3, p 148-151, March, 1982. 6 Fig, 3 Tab, 4 Ref.

Descriptors: *Coagulation, *Sludge excess, Water treatment, Cost analysis, Alum, Polymers, Orange County, North Carolina, Turbidity, Organic carbon.

Requirements of the 1977 Clean Water Act caused the Orange County, North Carolina, water authority, which discharged its sludge to a stream, to reduce the sludge volume from its water treatment plant by adjusting the coagulation regime. Total organic carbon and turbidity were most effectively removed and sludge production decreased by a combination of alum (30 mg per liter) and a high-molecular weight weakly-charged polymer (0.05 mg per liter). Best results were obtained when alum was added first, followed by polymer. Alum alone produced a difficult-to-dewater, voluminous sludge. Use of polymers alone removed less than optimum total organic carbon, and dosage requirements were high. Costs of the combined treatment for treating water with 27 NTU and 8 mg per liter total organic carbon at a flow rate of 0.24 cu m per sec were $80 per day, compared with $140 per day for alum alone. Costs were calculated using alum at 11 cents per kg and polymer at $6.56 per kg. (Cassar-FRC)

PERFORMANCE OF GRANULAR ACTIVATED CARBON FOR TOTAL ORGANIC CARBON REMOVAL,
Stanford Univ., CA. Dept. of Civil Engineering.
P. V. Roberts, and R. S. Summers.
Journal of the American Water Works Association, Vol 74 No 2, p 113-118, February, 1982. 12 Fig, 3 Tab, 21 Ref.

Descriptors: *Activated carbon, *Adsorption, *Organic carbon, Water treatment, Drinking water, Reviews, Mathematical studies, Kinetics, Performance evaluation, Water reuse, Costs, Regeneration.

An overview of a conference concerning the state of the art of oxidation and adsorption techniques in drinking water treatment uses total organic carbon (TOC) as a parameter for measuring removal of collected organics. A total of 47 data sets from 13 investigations (6 from the U.S. and 7 from Europe) were evaluated. Order-of-magnitude agreement was obtained over an extremely broad range of conditions. Partial breakthrough of TOC occurred immediately after startup. This was caused by the influent compounds, which were not amenable to removal by this method. A steady-state condition was attained after about 14,000 bed volumes. At this point, effluent TOC was 25% less than influent TOC because of biodegradation or slow mass transfer into micropores. Adsorption capacity was estimated by subtracting the amount of TOC removed by biodegradation from the total quantity of TOC removed. The adsorption equilibrium capacity calculated from breakthrough data agreed in order or magnitude with equilibrium isotherms measured in laboratory batch studies. Regeneration intervals in multiple paralled-operated units can be significantly reduced by blending the effluents from adsorbers regenerated sequentially. This is especially beneficial in larger plants, 10-38 ML per day capacity. (Cassar-FRC)

REACTIVITY OF HALOGENS WITH AQUEOUS MICROPOLLUTANTS: A MECHANISM FOR THE FORMATION OF TRIHALOMETHANES,
Poitiers Univ. (France). Lab. de Chimie de l'Eau et des Nuisances.
M. Ddore, N. Merlet, J. De Laat, and J. Goichon.
Journal of the American Water Works Association, Vol 74, No 2, p 103-107, February, 1982. 14 Fig, 1 Tab, 18 Ref.

Descriptors: *Trihalomethanes, *Chlorination, *Organic compounds, Chemical reactions, Disinfection, Water treatment, Chlorinated hydrocarbons, Chlorine, Bromine, Iodine.

The formation of trihalomethanes (THM) by chlorination of organic precursors during the water treatment process depends on many factors. Reactions carried out in stirred reactors showed that the yield of THM was proportional to the concentration of precursor (not necessarily identical to COD) and the quantity of chlorine available for reaction. Maximum yield of THM was obtained at near neutral pH for some precursors (acetylacetone and resorcine1) and at higher pH for other compounds. Some precursors reacted more rapidly with one halogen than another. For example, the methylketone reaction with iodine was much more rapid than the reaction with chlorine. The opposite was true for metapolyhydroxybenzene. Ammonia decreased the amount of THM formed from Cl and Br, but did not affect the reaction with iodine. The formation of total THM during chorination of natural water enriched with resorcinol and different doses of Br decreased with increasing Br concentrations. Under these conditions the chloroform concentrations decreased and bromoform and mixed organohalogen compounds increased. Conclusions reached from these experiments were as follows: (1) at the neutral pH values encountered in water chlorination some compounds such as methylketones present little danger of THM formation, but beta-diketones and metapolyhydroxybenzenes are reactive; (2) halogens react with ammonia in the order Cl > Br > I, and some chloroform is formed during chlorination of ammonia-containing waters; and (3) iodine can be used as a global test for determining THM precursors. (Cassar-FRC)

ADDENDUM TO: EVALUATING REGENERATED ACTIVATED CARBON THROUGH LABORATORY AND PILOT-COLUMN STUDIES,
I. H. Suffet, A. Wicklund, and B. Shultz.
Journal of the American Water Works Association, Vol 74, No 3, p 160, March, 1982. 1 Fig, 2 Ref.

Descriptors: *Activated carbon, *Regeneration, *Isotherms, Water treatment, Kinetics, Organic compounds, Methyl ethyl ketone, Adsorption, Trace levels.

An addendum to the original paper, Journal of the American Water Works Association, Vol 74, No 2, p 94, considers isotherm (capacity) and kinetic (column) factors in the evaluation of differing adsorbents. Freundlich isotherms were determined for each constituent of the 4-probe mix (methyl ethyl ketone, 1,4-dioxane, n-butanol, and nitromethane) on each sample of virgin and regenerated granular activated carbon. Four families of isotherms with roughly equal slopes but different vertical distribution were obtained. Nitromethane was not suitable as a probe for regeneration changes, because different regeneration techniques produced no apparent correlation with isotherms. However, methyl ethyl ketone isotherms were indicative of the regeneration methods. Results of the isotherm studies reiterated the general conclusions deduced from laboratory column studies in the original work. (Cassar-FRC)

MICROBIAL ACTIVITY IN ACTIVATED CARBON FILTERS,
Technische Hogeschool, Delft (Netherlands). Dept. of Civil Engineering.
J. G. den Blanken.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE2, p 405-424, 1982. 11 Fig, 4 Tab, 23 Ref.

Descriptors: *Activated carbon, *Water treatment, Filtration, Purification, Drinking water, Bacteria, Adsorption, Oxidation, Filter media.

The oxygen consumption and the removal of organic carbon as well as their relation to one another were studied to obtain information on the adsorption, bacteriological oxidation and desorption processes in filters. The measured oxygen consumption and pH decrease were the result of the bacteriological activity in the filters. The activity of the slow sand filter was comparable with that of the activated carbon filter in respect to bacteriological activity. In the carbon filter the physical and bacteriological processes have to be combined as well as possible. The bacteriological activity in filters can be increased by choosing carbon types with high adsorption capacity for bacteria and for easily degradable substances. To determine the contribution of bacteria to the purification capacity, both the oxygen consumption and the organics removal as well as their ratio have to be studied. In filters without phenol dose the oxygen consumption increased at a water temperature of 20 degrees C during the running time. The purification capacity and the running time are considerably increased by the bacteriological activity in the filters. The Norit RBW carbon type showed more intensive and more constant carbon removal and greater bacteriological activity than the Norit PK carbon types. With the help of phenol as a model substance the kinetics of the biological carbon filtration process can be studied. Under the influence of the copper dose, the pH of the water decreased. Numerous bacteria of various kinds are present on the carbon particles and can oxidize various organic substances. No indication was found that the bacteria present in the filters are harmful with regard to the consumption of the water. (Baker-FRC)

TRIHALOMETHANES IN CHLORINATED COOLING WATERS OF NUCLEAR REACTORS,
Du Pont de Nemours (E. I.) and Co., Aiken, SC. Savannah River Lab.
G. J. Hollod, and E. W. Wilde.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 404-408, 1982. 1 Fig, 2 Tab, 7 Ref.

Descriptors: *Water treatment, *Chlorinated hydrocarbons, *Cooling water, Heated water, Water pollution sources, Fate of pollutants, Nuclear powerplants, Savannah River, Aiken, South Carolina, Organic compounds, Chlorination, Trihalomethanes.

Trihalomethanes (THM) were determined in cooling water before and after chlorination and in the river receiving effluent at the Savannah River nuclear plant, Aiken, South Carolina, in April and November 1980. THM levels (in micrograms per liter) were as follows: Savannah River upstream and downstream of the plant, < 1 to 2; unchlorinated cooling waters, < 1 to 2; chlorinated cooling waters, 12-58. No value exceeded the EPA drinking water guidelines of 100 micrograms per liter. Chloroform and dichlorobromomethane were most abundant, 86-92% and 7-13% of total THM, respectively. Laboratory chlorination experiments with cooling water samples showed that 65 C water produced higher THM concentrations than 25 and 45 C water. However, THM dissipated more rapidly at the higher temperatures than at the lower temperatures. (Cassar-FRC)

EGYPT TACKLES RURAL SUPPLY TASK,
G. Chernock.
World Water, Vol 5, No 3, p 37, 39, March, 1982.

Descriptors: *Water supply, *Rural areas, *Developing countries, *Egypt, Water treatment, Water distribution, Beheira Water Company, Rehabilitation.

Egypt is using the Beheira province as a pilot region for supplying water to poorly served areas. The semi-autonomous Beheira Water Company will control the daily operations of water supply and revenue collection. The projected work on this water system includes rehabilitation of 12 treatment plants and 106 boreholes, installation of 70,000 new water meters, addition of chlorination units to 70 boreholes, improvements in water treatment plant operation, addition of 250 km of distribution system to the present 1500 km, and leak repair. The goal is increasing the present 99,000 cu m per day to meet the needs of 3.5 million people by 1990, at which time 100% of urban households and 90% of rural households should have access to safe water. After water treatment and distribution problems have been solved, the company expects to tackle wastewater disposal. (Cassar-FRC)

RELATIONSHIPS BETWEEN RAW WATER QUALITY, TREATMENT, AND OCCURRENCE OF ORGANICS IN CANADIAN POTABLE WATER,
Health and Welfare Canada, Ottawa (Ontario). Environmental Health Directorate.
R. Otson, D. T. Williams, and D. C. Biggs.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 4, p 396-403, 1982. 6 Tab, 15 Ref.

Descriptors: *Organic compounds, *Water quality, *Chlorinated hydrocarbons, *Water treatment, Fate of pollutants, Seasonal variation, Chlorination, Trihalomethanes, Hydrocarbons, Aromatic compounds, Chloroform.

Raw and treated water samples from 30 Canadian water treatment plants were analyzed for total organic carbon and for volatile organics. Certain correlations with raw water quality and treatment methods were found. Generally, the highest organics levels were found in summer and in raw and treated river water. Lowest organic levels were in raw and treated groundwater. Treated water had lower or the same levels of total organics but higher levels of halogenated compounds than raw water. The organic materials most commonly found in treated water were chloroform and other halogenated compounds, benzene, toluene, and xylenes. Chlorine dosages ranged from 0.1 to 9.0 mg per liter. The higher dosages and demands usually resulted in high chloroform and bromodichloromethane levels in treated water. Relationships of several compounds with each other and with treatment methods and summer-winter were complex. For raw water there were no significant correlations of chlorine dosages and water quality with organics levels. (Cassar-FRC)

PROTECTING THE SOURCE,
Pirnie (Malcolm), Inc., White Plains, NY.
S. A. Roberts, and S. K. Krishnaswami.
Water/Engineering and Management, Vol 129, No 3, p 28-31, March, 1982. 2 Fig, 3 Tab.

Descriptors: *Water quality, *Management planning, Groundwater, Drinking water, Water resources development, Water demand, Water supply, Resources management.

The first step to be taken in assuring a safe and acceptable public water supply is protecting the quality of its source. Where existing sources are contaminated, properly engineered, built, operated and supervised treatment facilities are needed. Control of contamination must be accomplished by judicious management and oversight of land use and human activities within the watershed involved. Protection of the inland wetlands is vital, as these areas play an important role in natural ecological cycles in terms of water supply sources, plant and animal habitats, flood control, oxygenation of watercourses and entrapment of pollutants, as well as other human needs such as recreation. The Safe Drinking Water Act of 1974 recognizes the importance of source protection in maintaining and enhancing drinking water quality as well as in conserving and protecting groundwater supply. Proper forest management, the creation of vegetative buffer zones on the edges of reservoirs and water courses, and the control of the growth of urbanization consistent with these protective objectives are also essential in order for long term economic burdens to be minimized. Unauthorized disposal of sludge and solid, septic and hazardous wastes within the watershed must be closely tracked and controlled. Unathorized use of herbicides and pesticides must be stopped. Monitoring and inspection programs are vital. Such a program to control and guard the quality of the nation's water requires coordinated, well planned and carefully executed efforts on the part of many people. Such a program, however, would assure maximum protection and obviate the need for expensive water treatment facilities or alternative sources in the long term. (Baker-FRC)

PILOTING MAG-CARBONATE TREATMENT,
Dallas City Water Utilities Dept., TX.
T. E. Taylor, M. E. Bolding, and C. E. Stringer.
Water/Engineering and Management, Vol 129, No 4, p 50, 53-55, April, 1982. 1 Fig, 1 Tab.

Descriptors: *Water softening, *Magnesium carbonate, *Lime, Water treatment, Dallas, Texas, Sludge disposal, Calcium carbonate.

The magnesium carbonate water treatment process was tested in a pilot plant at the Dallas, Texas, Elm Fork plant. The process involves addition of lime and a soluble Mg salt to the raw untreated water. Calcium carbonate and magnesium hydroxide are precipitated. Mg is removed as the soluble Mg(HC03)3, and the CaC03 is recovered and recalcined. The process worked successfully at a feed rate of 60 ppm Mg as carbonate in normal waters and with addition of 15-20 ppm Mg as magnesium sulfate in waters of higher turbidity. Mg recovery was 90% or greater. Sludge production was 3100 lb dry solids per million gallons by the Mg process and 1407 lb per million gallons by the ferric sulfate process. Both processes had the same amount of final sludge disposal solids, but 55% of the Mg sludge was recoverable for reuse. Ultimate sludge disposal for the Mg process was 20-30% of the ferric sulfate process. Sludge recycle at 35-50% of formation rate produced a good particle size for filtration. Although the Mg process requires a larger staff and additional electric power, coagulant consumption and lagoon capacity are reduced. (Cassar-FRC)

CONVERSION OF RAPID GRAVITY FILTERS TO FULLY AUTOMATIC OPERATION USING A PROGRAMMABLE LOGIC CONTROLLER,
North Surrey Water Co. (England).
J. Bowyer-Lowe.
Journal of the Institution of Water Engineers and Scientists, Vol 36, No 1, p 56-62, 1982. 2 Fig.

Descriptors: *Automation, *Control systems, *Backwash, Filtration, Water treatment, Chertsey Works, Gravity filters, Water treatment facilities.

Operation of the 12 rapid gravity filters at Chertsey Works was automated by application of a programmable logic controller. Backwashing was based on monitoring of filter head loss and filtrate turbidity. The system may be manually controlled if necessary. In the 18 months of operation the logic controller has been 100% reliable in spite of a power failure. The program was not lost at this time. The system proved reliable, easy to program and modify, simple to commission, and reasonable in cost. (Cassar-FRC)

THE CHERTSEY AUTOMATION PROJECT AT NORTH SURREY,
K. Benjamin.

Journal of the Institution of Water Engineers and Scientists, Vol 36, No 1, p 43-56, 1982. 4 Fig.

Descriptors: *Automation, *Control systems, Water treatment, Water distribution, Computers, Chertsey Works, England, North Survey Water Company.

The North Surrey Water Company chose the Chertsey Works for installation of the first system using computers to control water treatment and distribution. This paper describes in detail all the preliminary feasibility and design studies which led to the installation of the system. The main components are: the master control center (microprocessor, storage, monitors, entry keyboard, printer, etc.), nine unit controllers exercising direct local control, and system development equipment for changing programs. The Motorola 6809 was the model chosen for the 14 microprocessors used in the system. The water system is automatically regulated according to predetermined operating levels and pressures. Close real-time servo control is only required for the high lift and gravel well pumps and for chlorine disinfection and residual control. The central controller provides commands to the unit controllers, which are in direct control of the processes. Unit controllers do not communicate with each other. All performance data is logged either automatically or by an operator, and a daily record is printed. (Cassar-FRC)

A PRELIMINARY ASSESSMENT OF MICHIGAN'S PHOSPHORUS DETERGENT BAN,
Michigan Dept. of Natural Resources, Lansing.
J. H. Hartig, and F. J. Horvath.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 193-197, February, 1982. 5 Fig, 1 Tab, 17 Ref.

Descriptors: *Phosphorus, *Detergents, *Water quality standards, *Michigan, Wastewater treatment facilities, *Great Lakes, Water quality control, Lakes, Water pollution control.

Michigan's October 1, 1977, ban on phosphorus-containing detergents has reduced total P loadings in the Great Lakes by 20%. Since the ban, total P levels in influents of 58 large wastewater plants in the state decreased 23%, from 6.5 to 4.8 mg per liter, and in effluents, 24%, from 21. to 1.7 mg per liter. P loadings from the Saginaw River to Saginaw Bay decreased 60% over 1976-1979 as a result of the detergent ban, upgraded wastewater treatment, and decreased in flow. P loading for the Detroit River to Lake Erie decreased 50% over the same period as a result of the ban and improved wastewater treatment.No changes in P levels have yet been documented in western Lake Erie. ALTERNATIVE APPROACH TO ASSESSING WATER QUALITY IMPACT OF WASTEWATER EFFLUENTS,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
G. F. Lee, R. A. Jones, and B. W. Newbry.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 165-174, February, 1982. 4 fig, 13 Ref.

Descriptors: *Water quality standards, *Decision making, *Risks, *Water pollution effects, Water quality control, Effluents, Ammonia, Chlorine, Wastewater, Hazard assessment, Toxicity, Environmental effects, Fate of pollutants, Water pollution control.

Water quality assessment should be based on the impacts of contaminants on the desired beneficial uses of the water by man, not on the total concentration of contaminants in a water sample. The hazard assessment approach provides a technically valid basis for evaluating the effects of a contaminant on water quality. It is a sequential, selective testing scheme used to develop information on the toxicology of a chemical and its fate in the environment so that a decision can be made concerning the environmental risks of discharging a chemical. A hazard assessment is conducted in tiers of increasing sophistication and detail with a decision point at the end of each tier. This greatly reduces unnecessary testing and the possibility of overlooking unacceptable risks to water quality. Decision choices at the end of each tier's testing are: not to discharge the substance, to restrict discharge, to allow unrestricted discharge, or to continue testing to gather more information. An exampple of this tiered hazard assessment scheme is given for discharge of toxic domestic wastewater effluent components (ammonia, nitrate, and residual chlorine) into a river. (Cassar-FRC)

ENHANCED BIODEGRADATION OF PESTICIDES IN SOIL TO ALLEVIATE CONTAMINATED RUNOFF,
Cornell Univ., Ithaca, NY. School of Chemical Engineering.
R. U. Edgehill, and R. K. Finn.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224569, Price codes: A03 in paper copy, A01 in microfiche. November 1981. 22 p 4 Fig, 15 Ref. OWRT A-090-NY(1).

Descriptors: *Soil contamination, *Microbial treatment, *Pentachlorophenol, Soil amendments, Spills, Treatment, *Pesticides, Soil water, Microbial degradation.

Soil inoculation may be a feasible method of rapidly removing some pesticides from contaminated soil in short-term situations, such as when a spill has occurred. Pentachlorophenol (PCP) was rapidly removed from laboratory and field soils by the use of a microbial inoculant. Direct inoculation of 1,000,000 PCP-degrading bacteria per gram of soil containing 120-150 ppm of the pesticide resulted in a PCP half-life of 15 hours under laboratory conditions, whereas the half-life was 14 days without inoculation. In a field test with approximately 100,000 PCP-degradating bacteria per gram of soil containing 100 ppm PCP, a half-life of 2 days was observed. Inoculation was also found to be effective in removing PCP from soil placed in an outdoor shelter. Even though this test was conducted during rather cool weather (8-16 degrees C) and the soil was shielded from the sun, a much more rapid rate of degradation was observed in test soil than in uninoculated control soil.

HYDROGEOLOGY FOR LAND-USE PLANNING: THE POTTER CREEK AREA, ANCHORAGE, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
R. P. Emanuel, and D. J. Cowing.
Geological Survey Water Resources Investigations 82-86 (open-file report), 1982. 4 Sheets, 14 Fig, 7 Tab, 15 Ref.

Descriptors: *Land use, *Water resources development, Planning, Groundwater, Water quality, Water pollution, Septic tanks, Wastewater disposal, Geohydrologic units, Surface drainage, Soil environment, Wetlands, Snowmelt, Erosion, Hydrologic budget, Urbanization, Land classification, Potential water supply, *Alaska, *Anchorage, *Potter Creek area, Chugach Mountains, *Geohydrology.

The U.S. Geological Survey and the Municipality of Anchorage, Alaska, jointly funded a study of the Potter Creek area to obtain hydrogeologic information for land-use planning. The study area comprises about 16 square miles, from Cook Inlet into the Chugach Mountains. Annual precipitation is about 30 inches, approximately twice that of the lower, main part of the Anchorage bowl. About 31 million gallons of water per day flow through the hydrologic system in the study area. Precipitation contributes 23 million gallons per day; outflow as streamflow is 17 million gallons per day. Surface and ground water were found to be of good quality. Domestic wells were the sole source of water supply in 1980 and most wells tapped bedrock. The average bedrock well is more than 200 feet deep and yields 4.5 gallons per minute; the average well tapping unconsolidated sediments is less than 100 feet deep and yields 7.5 gallons per minute. Wetlands and areas of shallow ground water occupy about 24 percent of the study area. Landslope exceeds 20 percent in more than half the study area. Bedrock is exposed in about a third of the study area. Where maps indicate wetlands or shallow ground water, moderate to steep slopes, shallow bedrock, or surficial materials of low permeability, site-specific investigations can determine suitability for development. HYPOLIMNION OXYGENATION STUDIES IN CLARK HILL LAKE,
Drexel Univ., Philadelphia, PA.
R. E. Speece, C. Givler, R. Aubert, J. Crate, and R. Caire.
Journal of the Hydraulics Division, Proceeding of the American Society of Civil Engineers, Vol 108, No HY2, p 225-244, February, 1982. 17 Fig, 12 Ref.

Descriptors: *Dam effects, *Oxygenation, *Dissolved oxygen, *Hypolimnion, *Water quality control, Dams, Environmental effects, *Fisheries, Thermal stratification, Water quality management, Reservoirs, Lakes.

Large impoundments used for generating hydroelectric power usually have intakes located low on the dam face. After summer stratification of the reservoirs, hypolimnion water is discharged through the turbines, providing a cold water fishery below the dam. Oxygen depletion within the hypolimnion results in low dissolved oxygen (DO) levels in the waters being discharged, which affects water quality as well as downstream fisheries. The economic feasibility of injecting commercial oxygen into the reservoirs was studied in pilot tests conducted at Clark Hill Lake at the Clark Hill Dam, Georgia. Oxygen was injected 130 ft below the surface of the lake at a rate of 100 tons/day (90,700 kg/day) through a diffuser system extending 2,000 ft across the lake 1 mile upstream from the dam. DO was tested in each of the seven turbine discharges to evaluate the efficacy of the system in achieving a 6 milligrams/liter DO standard for discharges below the dam. Hypolimnion oxygenation by on-site production of cryogenic oxygen was estimated to cost $30/ton. An added 6 milligrams/liter DO with 85% absorption efficiency was produced by pulsed oxygen at a rate of 100 tons/day one mile above the dam resulted in a 50% loss of injected oxygen. (Geiger-FRC)

UTILIZATION OF ORGANIC PHOSPHATES BY SELECTED BACTERIA AND ALGAE,
Wroclaw Technical Univ. (Poland). Inst. of Inorganic Chemistry and Metallurgy of Rare Elements.
I. Langowska.
Water Research, Vol 16, No 2, p 161-167, February, 1982. 1 Fig, 3 Tab, 21 Ref.

Descriptors: *Phosphates, *Biodegradation, Eutrophication, Water quality, Organic compounds, Reservoirs, *Bacteria, *Algae.

A study was designed to find out whether synthetic phosphates may act as a source of carbon for bacteria isolated from a water reservoir. Studies also were made to determine whether the organic phosphates used could be utilized directly by algae or whether bacteria capable of forming phosphatase enzymes must coparticipate in this process by means of metabiosis. Respiration rates were examined in four bacterial strains for which the only sources of carbon were the phosphorus compounds under study. Glucose was the control. The respiration activities of the four species were different, with the highest activity in glucose being found in Bacillus coagulans. The synthetic surface active agents were relatively readily oxidized by aquatic bacteria. Bacillus coagulans appeared to be the most active of the strains, used since the quantities of oxygen consumed during respiration were much higher than with other bacteria. The effect of phosphorus compounds on growth of algae in pure culture was compared with that on growth of algae in the presence of four bacterial strains. The results indicated that the algae were able to use directly all of the organic compounds studied as a source of phosphorus, except for poly(oxyethylene)dodecylphosphoric acid. The quantity of biomass produced expressed in terms of chlorophyll content varied for different compounds, which indicates that a given compound was more or less available as a source of phosphorus. Good growth of algae in nonbacterial cultures proves that algae possess suitable phosphatases which enable them to utilize a specific organic compound. Not only bacteria but also autotrophic algae may participate in the biodegradation process of organic phosphates, even those which exhibit unfavorable chemical properties for living organisms. PERFORMANCE TESTING OF THE DIPERNA SWEEPER,
Mason and Hanger-Silas Mason Co., Inc., Leonardo, NJ.
M. K. Breslin.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-109174, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protect Agency Project Summary EPA-600/S2-81-229, December 1981, 8 p, 4 Fig, 2 Tab. 68-03-2642.

Descriptors: *Oil skimmers, *Oil recovery, *Cleanup operations, Oil spills, Water pollution control, Wave action.

The DiPerna Sweeper, a partial-vacuum oil skimmer, was tested in a 2-week program conducted at the Oil and Hazardous Materials Simulated Environmental Test Tank (OHMSETT). Forty-three oil recovery tests were run to establish a range of best performance for the skimmer under various environmental conditions in light and heavy oil. The DiPerna Swepper is a self-contained, floating oil skimmer that can operate in either a stationary or advancing mode. Its principle of operation is based upon drawing oil and water into a sealed container by creating a slight vacuum in the container. A floating weir serves as the inlet. The partial vacuum is crated by pumping fluid from the sealed container. The container serves as an oil/water separator. Separator pumps draw water from the bottom of the vessel while others draw oil from the top. The device was able to recover over 75% of the oil presented to it in calm water at low speeds up to 2 knots. The skimmer performed best in high viscosity oil in calm water, and has the capability of collecting oil with less than 5% water. A rdesign of the skimming head and inlet hose should be undertaken to improve the skimming head water ballasting system, to prevent wave splashover response and to prevent turbulence and headwave production while under tow. (Moore-SRC)

PERFORMANCE TESTING OF FOUR SKIMMING SYSTEMS,
Mason and Hanger-Silas Mason Co., Inc., Leonardo, NJ.
H. W. Lichte, M. K. Breslin, and G. F. Smith.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-101353, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-189, October 1981. 8 p, 5 Fig, 4 Tab. 68-03.2642.

Descriptors: *Oil skimmers, *Oil recovery, *Cleanup operations, *Water pollution control, Oil spills, Wave action, Viscosity, Entrainment, Comparison studies.

A test program conducted during the 1979 season evaluated skimmer performance in collecting oil floating on water using several wave conditions, two speeds, and skimmer operating parameters. Tests were conducted at the Oil and Hazardous Materials Simulated Environmental Test Tank (OHMSETT) on four commercial oil spill cleanup devices. In tests with the Sapiens Sirene, the highest values of recovery efficiency (RE), throughput efficiency (TE), and oil recovery rate (ORR) were obtained during tow tests with waves. Medium viscosity oil was entrained and lost from the system more easily than high viscosity oil because of interfacial shear forces. No oil was lost because of wave splashover. Tests were conducted with the Oil Mop remote skimmer in order to generate design information for future construction of a larger version. The operating limits for this skimmer appeared to depend on two factors; oil mop contact time, and slippage of oil-soaked mops through the squeezing roller assembly. The Troil/Destroil skimmer system has the following operating limits; the maximum towing speed at which the boom can retain collected oil without significant loss is 1 knot; and the maximum pumping rate of the skimmer pump is approximately 37.4 cu m/hr. The versatile Environment Products Arctic Skimmer should be operated at speeds not greater than 2 knots for high efficiency, and to maintain high recovery efficiency a thick oil layer should be maintained at the collection belt. The oil recovery rate of the skimmer is limited by the maximum pumping rate of the skimmer pump. (Moore-SRC)

REMOVAL OF WATER SOLUBLE HAZARDOUS MATERIALS SPILLS FROM WATERWAYS BY ACTIVATED CARBON,
Rockwell International, Newbury Park, CA.
G. R. Schneider.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-103813, Price codes: A04 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-195, October 1981. 6 p, 5 Fig, 1 Tab. 68-03-2648.

Descriptors: *Hazardous materials, *Cleanup operations, *Activated carbon, *Organic compounds, *Phenol, Spills, Waterways, Mathematical models, Turbulence, Adsorption.

A model of the removal of water soluble organic materials from water by carbon-filled, buoyant packets and panels was developed. Based on this model, equations were derived for removing dissolved organic compounds from waterways by buoyant packets that are either cycled through a water column, or suspended in the waterway by natural turbulence and by panels mechanically suspended in waterways. Assuming that response is required within 1 to 8 hr to an 1,814-kg phenol spill into the Chicago Sanitary and Ship Canal (CSSC), packet cycling with 18,140 kg of activated granular carbon in 897,000 buoyant packets, would require 155 to 368 cycles to effect a 10% reduction in concentration. If it were possible to keep the buoyant packets suspended in the CSSC by turbulence, a response to a 1,814 kg spill in 1 to 8 hr would produce a situation requiring 25 to 60 hr to remove 10% of the spilled phenol, even if the dispersion process were to cease.. A continuing dispersion process will prevent the success of a carbon filled packet approach to cleanup. Carbon panels fixed in a watercourse the size of the CSSC will remove about 4% to a 1,814 kg phenol spill as the polluted fluid passes by the panels, according to the model, if the carbon to phenol ratio is 10. (Moore-SRC)

DEPLOYMENT CONFIGURATIONS FOR IMPROVED OIL CONTAINMENT WITH SELECTED SORBENT BOOMS,
Mason and Hanger-Silas Mason Co., Inc., Leonardo, NJ.
G. F. Smith.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-210650, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-168, October 1981. 3 p. 68-03-2642.

Descriptors: *Oil spills, *Cleanup operations, *Oil recovery, *Water pollution control, Containment booms, Harbors, Wave action, Sorbent booms.

Performance tests on three catenary oil containment configurations using sorbent boom sections alone and in conjunction with a conventional containment boom were conducted at the Oil and Hazardous Materials Simulated Environmental Test Tank (OHMSETT). Other test varables included wave condition, tow speed, and oil quantity encountered. Maximum no-oil-loss containment tow speed was determined for each wave and oil quantity tested. Use of a sorbent raft inside the apex of a catenary, conventional oil containment boom failed to increase the maximum no-oil-loss tow speed; in fact, no-oil-loss tow speeds increased with the use of sorbent raft apex sections. Conventional boom sides coupled with a sorbent raft apex section increased the no-oil-loss tow speed in calm water and 100% oil capacity from 0.25 m/s for a single-layer totally sorbent boom to 0.29 m/s for a four-layer sorbent raft apex section. similar tests in the 0.3-m harbor chop (HC) wave exhibited a no-oil loss tow speed increase from 0 m/s to 0.22 m/s. Loss of oil occurred mainly at the attachment points of the sorbent raft to the conventional boom sides. Tests using an all sorbent boom with a five-layer sorbent raft apex caused increases in no-oil-loss tow speeds to 0.33 m/s in calm water and 0.17 m/s in the 0.3-m HC.. Attempts at boom regeneration were futile. (Moore-SRC)1c

USE OF SELECTED SORBENTS AND AN AQUEOUS FILM FOAM ON FLOATING HAZARDOUS MATERIALS,
Mason and Hanger-Silas Mason Co., Inc., Leonardo, NJ.
M. K. Breslin, and M. D. Royer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-108895, Price codes: A04 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-211, October 1981. 6 p, 7 Fig. 68-03-0490.

Descriptors: *Hazardous materials, *Cleanup operations, *Spills, Water pollution control, Wave action, Adsorption, Naphtha, Octanol, Dioctyl phthalate, Vaporization, *Sorbent materials.

In order to enhance present techniques for handling spills of floating, immiscible hazardous materials, tests were conducted on the effects of sorbent materials and firefighting from on containment, recovery, and vapor suppression. Dioctyl phthalate (DOP), octanol, and naphtha served as the hazardous materials. The sorbent materials were polyurethane foam cubes, Sorbent C, and dow Imbiber beads. As aquesous film forming foam (AFFF), FC-206 was used. Results indicate that introducing sorbents or congealing agents into the hazardous material enables a stable boom to contain the material at a higher current velocity or

tow speed in calm water. The polyurethane foam cubes were most easily distributed and accounted for later. To optimize the effect of sorbents, time for mixing and adsorption of the hazardous material must be allowed. Because the splash-over failure, neither the sorbents nor the Imbiber beads enhanced containment in the presence of 0.3-m harbor chop. Cleanup effort was substantially increased as a result of the use of sorbents. Some tests results indicate that a higher critical tow speed is attainable using AFFF and sorbent rather than sorbent alone. (Moore-SRC)

OIL SLICK MECHANICS,
Rutgers - The State Univ., Brunswick, NJ.
C. A. Osamor, and R. C. Ahlert.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-105560, Price codes: A11 in paper copy, A01 in microfiche. Environmental Protection Agency Summary EPA-600/S2-81-199, October 1981. 3 p. R805901.

Descriptors: *Oil slicks, *Oil spills, *Dispersants, *Solubility, *Oil-water interfaces, Cleanup operations, Mathematical models, Saline water, Hydrocarbons, Surface tension, Water pollution control.

Oily discharges to aquatic systems are usually marked by slick formation. The potential for damage by oil spills depends on the rates of the dispersal mechanisms and other factors. Spreading and dissolution of oils in the underlying water are important dispersal mechanisms. The rates of dissolution and spreading of 12 oils were investigated under laboratory conditions. Mathematical models were derived for oils spreading on calm water. The principle forces influencing the spread of oils on calm water are gravitational, viscous, inertial, and net surface tension. The dissolution rates of the oils were determined by measuring their solubilities in water during equilibration in open static tests. Experimental data show increases in oil concentrations initially and decreases later during the period of equilibration. Solubilities were lower in tests with salt water, and the oils attained maximum solubilities at slower rates. Data suggest that as oil slicks equilibrate with water, volatile hydrocarbon species evaporate into the atmosphere from the air/oil interface, and soluble species dissolve into the underlying column of water from the oil/water interface. These processes are not in equilibrium; hydrocarbons continue to evaporate from solution after the oil layer has been depleted of volatile hydrocarbons. The efficiencies of five commercial products for dispersing three oils were evaluated in a large-scale laboratory system. Efficience was found to increase with the volume of dispersant added. The dispersal of spilled oil by application of chemical dispersants appears to be a promising method for cleaning up oil spills. (Moore-SRC)
W82-05064

FEASIBILITY OF COMMERCIALIZED WATER TREATMENT TECHNIQUES FOR CONCENTRATED WASTE SPILLS,
TRW Environmental Engineering Div., Redondo Beach, CA.
M. Ghassemi, K. Yu, and S. Quinlivan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-108440, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-213, October 1981. 6 p, 4 Tab, 68-03-2560.

Descriptors: *Wastewater treatment, *Hazardous materials, *Spills, *Cost analysis, *Feasibility studies, Reverse osmosis, Ultrafiltration, Ion exchange, Oxidation, Activated sludge processes, Coagulation, Mobile systems, On-site systems.

Data from the published literature and those obtained from process suppliers provided the data basis for an evaluation of commercial water treatment techniques for on-site treatment of waters containing high concentrations of contaminants that are encountered in hazardous materials spill situations and at uncontrolled waste disposal sites. The techniques include reverse osmosis, ultrafiltration, ion exchange, wet-air oxidation, high-purity oxygen-activated sludge process, ultraviolet-ozone oxidation, and coagulation/precipitation. When used alone, none of the processes considered would be economically applicable to on-site mobile unit treatment of the variety of concentrated wastes encountered, although reverse osmosis, ion exchange, and wet-air oxidation meet many of the application requirements and, hence, require less pretreatment, or post-treatment. The estimated capital costs for a unit suitable for trailer mounting vary from as low as $35,000 for a 227,000 L/day ultrafiltration unit to as high as $1.25 to $1.5 million for a 54,000 L/day two-trailer, wet-air oxidation unit. For short-term operation, the operating cost of the mobile unit is determined largely by nonprocess-specific costs such as transportation, labor, subsistence, analytical support, which vary from situation to situation. (Moore-SRC)
W82-05068

DISPERSANT APPLICATION SYSTEM FOR THE U.S. COAST GUARD 32-FOOT WPB,
Mason and Hanger-Silas Mason Co., Inc., Leonard, NJ.
M. Borst, and G. F. Smith.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-101684, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-172, October 1981. 2 p 1 Fig. 68-03-2642.

Descriptors: *Dispersants, *Oil spills, *Cleanup operations, Water pollution control, Waterways, Oil pollution.

A lightweight, easily assembled system for dispensing chemical dispersants on oil spills was designed to be fitted onto the aft deck of the Coast Guard 32-foot waterways patrol boat (WPB), a vessel stationed in many areas where oils are commonly transferred or transported. It includes two spray booms supported by a rectangular framework. The spray booms are supplied water from the boat's fire fighting system, and chemical dispersant is fed into the water by an eductor. The system could readily be adapted for use on other vessels of opportunity. The only limiting conditions are the ability to provide sufficient height for the spray booms and structural integrity. The system needs an adequate supply of water from an onboard source. For example, the end sections of the support frames could be lashed to the side handrails of most vessels with fore and aft stays secured as convenient. (Moore-SRC)

A MOBILE STREAM DIVERSION SYSTEM FOR HAZARDOUS MATERIALS SPILLS ISOLATION,
Scientific Service, Inc., Redwood City, CA.
J. V. Zaccor.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-109679, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-219, October 1981. 3 p, 1 Fig, 1 Tab. 68-03-2458.

Descriptors: *Cleanup operations, *Diversion, *Stream pollution, *Hazardous materials, Isolation, Decontamination, Pumps, Pipes, Conveyance structures, Mobile systems,.

Spill cleanup scenarios often involve contamination of small streams by insoluble, sinking hazardous materials. One cleanup approach is to dam the stream above the affected area and bypass the normal flow; this procedure allows the contaminated stream to dry and, thus, facilitates mechanical cleanup. Spill scenarios were analyzed to establish designcriteria for a completely self-contained, independent system that would maintain flow continuity around a region undergoing decontamination processing. The system was designed to use stock items available nationwide, to be easily maintained, and to be readily repairable. To provide flexibility and reliability, the system has been assembled as two totally independent units mounted on trailers. These trailers do not require permits for hauling over state or interstate highways and they can also be moved over unimproved roads to gain access to spill sites. Once onsite, the system can be assembled and placed in operation by a crew of five in a matter of hours. Unit operation and ability to deliver a flowrate of 0.35 cu m a distance of 0.3 km over unprepared ground were evaluated in a shakedown test. The major components of the system are: booster pumps; submerisble pumps; generator; pipes, hose, and fittings; crane; transportation system; and lighting system. (Moore-SRC)

THE EFFECTS OF VARYING CULTURE NITROGEN AND PHOSPHORUS LEVELS OF NUTRIENT UPTAKE AND STORAGE BY THE WATERHYACINTH EICHHORNIA CRASSIPES (MART) SOLMS,
University of the Witwatersrand, Johannesburg (South Africa). Dept. of Botany and Microbiology.
J. Ower, C. F. Cresswell, and G. C. Bate.
Hydrobiologia, Vol 85, No 1, p 17-22, 1981. 2 Fig, 2 Tab, 11 Ref.

Descriptors: *Water hyacinth, *Nutrient removal, *Eutrophication, Aquatic plants, *Nitrogen, *Phosphorus, Fertilizers, Water pollution treatment, Water treatment.

Water hyacinths were cultured for one month in solutions with nutrient levels varying from zero phosphorus and nitrogen to 16.1 ppm P and 36 ppm N. Maximum uptake by the plants was in a culture solution containing 36 ppm N and 6.53 ppm P. Uptake of P was stimulated by elevating either N or P levels or both. N accumulation was inhibited at all levels of P addition. Both N and P levels were highest in leaves and d lowest in roots. The ability of the water hyacinth to accumulate nutrients from eutrohied bodies of water indicates a possible use of this plant for nutrient removal and harvesting as fertifilizer. (Cassar-FRC)

Hydrotechnical Construction, Vol 15, No 6, p 319-323, June, 1981. 1 Tab, 11 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 8-11, June, 1981.

Descriptors: *Alagal harvesting, *Eutrophication, *Lakes, Algal control, Water pollution control, *Water quality control, Reservoirs, Cyanophyta, Nutrient removal.

Suggestions for improving the quality of lake and reservoir water in the presence of blue-green algal blooms include reduction of nutrients in water and wastewater entering the reservoirs, construction of buffer zones of trees and grass around water bodies to filter out nutrients draining into the water bodies, use of improved slow-release and encapsulated fertilizers, improvement of fertilizer application techniques to minimize fertilizer losses, aeration of natural water, and large scale removal of excess plant material from eutrophic water bodies. As an example of the last technique, removal of 1 ton of dry seston eliminates 50-150 kg N, 10 kg, P, 50-60 kg of other minerals, and 200-400 kg of organic matter. Removal of 1 kg P leads to a 100 kg decrease in algal production. (Cassar-FRC)

Descriptors: *Mine drainage, *Neutralization, *Acid mine drainage, Ponds, Settling ponds, Water treatment, *Calcium carbonate, Calcium hydroxide, *Coal mining, Strip mine lakes, Hydrogen ion concentration, Barton County, *Missouri.

It was necessary to neutralize an acid settling pond (pH 2.6) in Barton County, Missouri, before drainage for reconnaissance investigations. Instead of the recommended method of adding lime and calcium carbonate in situ, a two-stage neutralization was done. First 13 tons of calcium carbonate was spread over the water, raising the pH from 2.6 on September 15, 1980, to 4.3 on September 16. The water was then pumped 800 ft into an empty receiving pond in which 10 tons of calcium carbonate had been spread. The entering water flowed over the spread limestone. Turbulence accelerated the escape of carbon dioxide into the atmosphere, driving the neutralization reaction toward completion. The pH of the water was 5.6 by the afternoon of September 16. Costs were 80% less than estimated for the in situ method. After 3 weeks the receiving pond water had a pH of 5.3-6.8. (Cassar-FRC)

HANDBOOK FOR OIL SPILL PROTECTION AND CLEANUP PRIORITIES,
Versar, Inc., Springfield, VA.
J. D. Byroade, A. M. Twedell, and J. P. LeBoff.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-183394, Price codes: A07 in paper copy, A01 in microfiche. Environmental Protection Agency Report EPA-600/8-81-002, February 1981. 142 p, 12 Fig, 34 Tab, 44 Ref, 6 Append. 68-03-2648.

Descriptors: *Oil spills, *Cleanup operations, *Water pollution control, *Priorities, Decision making, Environmental effects, Natural resources, Oil pollution, Environmental protection.

Any oil discharge into marine or fresh water systems will inevitably affect both natural and man-made resources. Ideally, all potentially affected resources should be protected from damage, but usually some priorities must be set to adequately use the available manpower and equipment for resource protection. Responsibility for determining priorities for both protection and cleanup lies with the designated on-scene coordinators (OSC). This manual was developed for use by OSC to guide them in assessing priorities during all phases of an oil spill reponse. The guidelines enable the OSC to: determine pertinent facts about a particular oil discharge; identify the resources and installations that may be affected; and establish priorities for protecting and cleaning up these sensitive resources and installations. Special attention is given to response activities such as: determining spill contamination potential; rating area sensitivity to oil contamination; establishing priorities for containment, protection, and cleanup; deciding the best practical containment, protection, and cleanup methods, assessing response effectiveness; and deciding when to terminate cleanup efforts. THE REHABILITATION OF NORWAY'S LARGEST LAKE,
Norsk Inst. for Vannforskning, Oslo.
K. Baalsrud.
Water Science and Technology, Vol 14, No 1/2, p 21-30, 1982. 5 Fig, 3 Tab, 8 Ref.

Descriptors: *Eutrophic lakes, *Phosphorus removal, *Lake restoration, Water pollution effects, Lakes, *Lake Mjosa, *Norway, Eutrophication, Water quality management, Phosphates, Algae, Geosmin, Wastewater treatment.

Lake Mjosa, Norway's largest lake, is long and narrow, with a water volume of 56 cu km and maximum depth of 449 m. Eutrophication, first noticed in the 1960's, progressed to the point of severe algal blooms and formation of geosmin, which made the water undrinkable. Restoration started in 1977 with two objectives: develop wastewater treatment systems and remove phosphorus. Forty-six new treatment plants and 500 km of new sewer pipes were installed, so that 105,000 people of the 115,000 living in urban areas were included in the phosphorus control program as of 1980. Home wastewater treatment for the 85,000 person rural population of the area was financed through direct grants and low-interest loans. Pollution controls were implemented in agriculture and industry. Use of phosphate-free laundry detergents was encouraged. By 1980 the P load was reduced to about 225 tons per year (the goal is 175 tons per year). Signs of eutrophication have been much less apparent. Some blue-green algae are still present, but in small numbers, and lake transparency has improved. In 1980 algal biomass had dropped to 0.8 cu mm per liter from a high of 1.7 cu mm per liter in 1978. Under oligotrophic conditions in 1900 algal biomass was 0.2 cu mm per liter. (Cassar-FRC)

WATER-POLLUTION RESEARCH AND ITS APPLICATION IN DEVELOPING COUNTRIES,
Newcastle upon Tyne Univ. (England). Dept. of Civil Engineering.
P. Isaac, and W. Pescod.
Water Science and Technology, Vol 14, No 1/2, p 205-213, 1982. 1 Ref.

Descriptors: *Research priorities, *Developing countries, *Water pollution control, Wastewater treatment, Sanitation, Water pollution sources, Political aspects, Economic aspects, Social aspects, Institutional constraints, Information exchange, Planning, Rural areas.

Water pollution research for developing countries must be directed toward practical applications, taking into consideration the social, political, religious, and financial factors in these poorer rural areas. Sources of pollution in these countries are poor sanitation and disposal of human wastes, industrial effluents, and organically-loaded effluents from food processing (sugar cane, palm oil, and tapioca). Water pollution control efforts by governments are inadequate and ineffective. Research for Third World countries should emphasize development of simple, low-cost systems rather than esoteric subjects such as reaction kinetics. The simple systems should be designed with upgrading in mind. Urban areas can use conventional systems without further research efforts. Demonstration projects are ideal for convincing government officials and local populations of a treatment system's potential. Ex-post-facto analysis of projects too elaborate, too expensive, or unacceptable for social reasons can prevent perpetuation of mistakes. Information transfer throughout the developing world must be facilitated through conferences, organization of published literature, and publishing of research papers by Third World authors. (Cassar-FRC)

AMMONIUM UPTAKE BY MICRONESIAN SPECIES OF GRACILARIA (RHODOPHYTA),
Guam Univ., Agana. Water and Energy Research Inst.
S. G. Nelson, and R. N. Tsutsui.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224858, Price codes: A02 in paper copy, A01 in microfiche. Final Report, Technical Report No 23, May, 1981. 13 p, 3 Fig, 2 Tab, 20 Ref. OWRT A-019-GUAM(1), 14-34-0001-0112.

Descriptors: *Absorption, *Ammonium, *Nitrogen removal, *Bacterial analysis, *Microorganisms, Regression analysis, Nitrogen compounds, Nitrogen fixing bacteria, Water analysis, Kinetics, Biological properties, Water quality, Bioassay, Correlation analysis, Correlation coefficient, Mathematical studies, Evaluation, Baseline studies, *Guam.

Research was carried out to examine the kinetics of ammonium uptake by thalli of several Gracilaria species from Micronesia to evaluate their relative potential for removing ammonium from mariculture systems. It was found that ammonium uptake was dependent upon substrate concentration, and that the uptake kinetics were consistent with a diffusive ammonium uptake process, as shown for ammonium depletion curves of ammonium concentration versus time for each species. Regressions of the log of substrate concentration with time were linear, with correlation coefficients ranging from 0.913-0.996. Uptake rates were independent of light, and were similar during both day and night. Uptake rates were also independent of the thalli nitrogen content. The observed rates of uptake were generally higher for Gracilaria edulis than for other Gracilaria species. The latter observation may be related to thallus morphology. The uptake rates (micrograms ammonium/gram dry thallus/hour) ranged from 0.810-2.184 for Gracilaria edulis, and 0.086-0.722 for other species. The thalli of the Gracilaria species were collected from various locations in Guam and Saipan in the Mariana Islands, and near Malakal Island, Palau. (Zielinski-MAXIMA)

Descriptors: *Reservoirs, *Urban drainage, *Lake Houston, Phosphorus, Nitrates, Sedimentation, *Sediments, Drainage, Water quality, Water supply, Eutrophication, Turbidity, Watershed protection, Texas, *Nutrients, Environmental effects.

This study characterized the lake hydrology and developed nutrient and sediment budgets for Lake Houston, quantified algal productivity as it related to lake water quality characteristics, and suggested a set of management strategies for developing areas to improve the water quality in the lake. The lake was formed in 1954 by an earthfilled dam on the San Jacinto River. Storage capacity of the lake is about 146,800 acre-feet at spillway level and has a surface area of 12,765 acres. Maximum depth is close to 45 ft at the dam, with mean depth of only 12.5 ft. Total drainage area of the lake is 2,828 sq mi and can be divided into the two forks of the San Jacinto River. Most of the solids that come into the lake remain there, while most of the nitrates and half the total phosphorus are lost over the spillway. Sedimentation is controlled by bathymetry, energy and distribution of wind generated waves, location of relict sediments, proximity to sediment source, and man-made barriers. Lower water quality was observed in the West Fork, which represents a rapidly urbanizing area, as compared with the East Fork, which represents an undeveloped, mostly forested area. Storm flows are extremely important because of the washout effect they have on algae and the turbidity that is usually associated with them. Low flows are also important, as they represent critical periods when suspended solids start to settle and more light is allowed to penetrate the water column. Principal management strategies available involve sediment or nutrient load control. Sediment control may be attained by using a system of detention ponds. Nutrient loads can be reduced significantly by better operation of wastewater treatment plants. (Baker-FRC)

SETTLEABILITY OF URBAN RUNOFF POLLUTION,
Rutgers - The State Univ., New Brunswick, NJ. Water Resources Research Inst.
W. Whipple, Jr., and J. V. Hunter.
Journal of the Water Pollution Control Federation, Vol 53, No 12, p 1726-1731, December, 1981. 9 Fig, 14 Ref.

Descriptors: *Urban runoff, *Sedimentation rates, *Water pollution sources, Watershed protection, Settleable solids, *Detention reservoirs, Suspended solids, Storm runoff.

The possibility of using dual purpose detention basins for the removal of particulate pollution from

urban runoff is currently under investigation. Tests of urban runoff were conducted to measure the removal of different types of pollutants by sedimentation. Sampling was conducted in five intensively developed areas. Analyses were conducted to determine total phosphate, fecal coliform counts, suspended solids, 5 and 20 day biochemical oxygen demand, nitrates, heavy metals, hydrocarbons, and ammonia. These studies showed that detention of runoff in an undisturbed environment with a water depth of 6 feet for 32 hours resulted in removal of substantial quantities of the common pollutants associated with urban runoff. The settleability data for pollutants showed more scatter than data for total suspended solids. The data for suspended solids, hydrocarbons, and lead indicated that most of the sedimentation of these pollutants was accomplished in 16 hours, but results for other pollutants, particularly copper, were more irregular. Considerable variation was found in the settleability of runoff from different sites. The results of this study did not support the common assumption that pollutants will settle out in amounts proportionate to their respective particulate concentrations. (Carroll-FRC)

OPTIMAL DYNAMIC MANAGEMENT OF GROUNDWATER POLLUTANT SOURCES,
Geological Survey, Menlo Park, CA.
S. M. Gorelick, and I. Remson.
Water Resources Research, Vol 18, No 1, p 71-76, February, 1982. 6 Fig, 2 Tab, 18 Ref.

Descriptors: *Solute transport, *Water quality management, *Disposal wells, *Wastewater disposal, Fate of pollutants, Waste management, Wastewater management, Waste disposal, Model studies, Injection wells, Wells, *Groundwater pollution.

A linear programming-superposition method is presented for optimum management of several groundwater pollutant sources (for example, waste disposal) over time so that maximum disposal is accomplished without violating water quality standards. It uses any linear solute transport simulation model to generate a unit source-concentration response matrix to derive the management model. Special simulation model development is not required. The constraints take the form of a series of solute breakthrough curves at supply wells where water quality must be maintained. The matrix shows the concentrations that result at particular locations from solute injections at each of the disposal sites over time. The linear program operates on the matrix to obtain optimal disposal schedules. The method is applied to a sample problem in which three water supply wells must be protected from pollutants injected into three disposal sites over three continuous 200-day periods. (Cassar-FRC)

Descriptors: *Water quality management, *Sediment transport, *River beds, *Danube River, Model studies, Water supply, Filtration, Bank filtration, Suspended solids, Water pollution control, Fate of pollutants, Adsorption.

A water management system for the Danube River is proposed. This is not based on the classification of surface waters but on the morphological, hydrological, hdyraulic, and technological conditions of drinking water production. The role of micropollutants adsorbed to sediments, neglected in former management schemes, is considered in determining the quality of the bank filtered water supply. A transport model consists of several submodels, including water regime of the river, pollutant dispersion, settling and reentrainment, chemical interactions between wastewater and river water, biochemical processes in bottom sediments, and groundwater flow toward the bank filtering wells. Canadian Water Resources Journal, Vol 5, No 2, p 54-67, 1980. 2 Fig, 2 Tab, 9 Ref.

Descriptors: *Storm wastewater, *Combined sewer overflows, Rideau River, Ottawa, Ontario, Bacteria, Planning, Recreation, Swimming, Water pollution control, Water pollution sources, Water quality control, Assimilative capacity, Storm-overflow sewers, Pollution load, Ponds.

Bacterial pollution of the Rideau River flowing through Ottawa, Ontario, forced closing of bathing beaches in 1970. The major pollution source was overflow from combined sewers during rainfall events. Abatement measures included separation of storm and sanitary sewers (scheduled for completion in 1990), installation of pumps to improve water circulation at the most upstream beach, closing of a small sanitary treament plant, and construction of ponds to reduce suspended solids and bacteria levels. A storm water management study of the Rideau River was initiated to study the magnitude and sources of pollutant loads and the hydraulic conditions of the river, to predict pollutant loads from future developments, to determine the assimilative capacity of the river, to determine the effectiveness of present storm water management, to assess the effectiveness and cost of control measures, and to clarify the recreational needs and most practical bathing areas. The 3-year, $1.4 million study began in June 1979. (Cassar-FRC)

Descriptors: *Lake restoration, *Aeration, *Nutrients, Water quality control, British Columbia, Wood Lake, Kalamalka Lake, Water pollution sources, Algae, Eutrophication, Nonpoint pollution sources, Transparency, Phosphorus, Nitrates.

Kalamalka and Wood Lakes, in the Okanagan Valley of British Columbia, are subject to excess nutrient inputs from agriculture and residential development and are separated by only a narrow strip of land. However, they are very different in water quality and morphometry and require different strategies to manage water quality. Kalamalka Lake, 25.8 sq km in area, 142 m deep, is extraordinarily attractive with clear water and low productivity. Wood Lake, 9.3 sq km, 34 m deep, has already suffered significant deterioration in water quality. Water quality control options in Lake Kalamalka are limited to source control (sewers, improved agricultural practices, green belting, erosion control, and improved water quality in Wood Lake). Smaller Wood Lake has several options for improving water quality. Control of internal loading by phosphorus stripping using alum, mixing with other lake waters, and tertiary treatment are impractical and expensive. Aeration may be the most practical method in spite of the 6000-7000 kg per day oxygen demand over the summer stratification period. Other techniques being considered are use of nutrient-rich hypolimnetic water for irrigation and addition of nitrates to the hypolimnion to stimulate the denitrification process. Since lake restoration is still an art in many ways, treatments must be chosen and applied cautiously to avoid adverse effects. (Cassar-FRC)

WHERE TO PUT A STEADY DISCHARGE IN A RIVER,
Cambridge Univ. (England). Dept. of Applied Mathematics and Theoretical Physics.
R. Smith.
Journal of Fluid Mechanics, Vol 115, p 1-11, 1982. 6 Fig, 11 Ref.

Descriptors: *Wastewater outfall, *Design criteria, Effluents, Outfall, Outfall sewers, Rivers, Water pollution control, Mathematical studies, Hydraulics, Wastewater discharge.

In order to avoid high pollution levels along the banks of rivers and streams it is desirable to release effluents from industrial processes and sewage works somewhere near the center of the receiving water body. The position of a single discharge point, or the distribution of multiple discharges, determines the way in which the asymptotic state is approached. The most ambitious target would be to minimize the peak concentration anywhere in the flow. This can be achieved if the discharge rate at each point across the flow is exactly matched to the local volume flow rate, that is, if the constant-concentration asymptote is attained immediately. A more practicable target is to restrict attention to a single discharge point and to minimize the peak concentration at the shoreline. In a straight channel with a symmetric depth profile the shoreline concentration would exhibit such an overshoot unless the outlet were positioned at the center. The question then becomes that of ascertaining the center of a non-symmetric or meandering river. The precise location of the optimal discharge site is at the single zero crossing of the first advection-diffusion eigenmode. Simple examples are described which reveal that this position tends to be weighted toward the inside bank at the beginning of bends. (Baker-FRC)

THE COST AND EFFECTIVENESS OF PUBLIC NOTIFICATION OF MCL VIOLATIONS,
Pittsburgh Univ., PA. School of Education.
C. E. Stegman, and G. Schneider.
Journal of the American Water Works Association, Vol 74, No 2, p 59-65, February, 1982. 9 Tab, 2 Ref.

Descriptors: *Water quality standards, *Public relations, Public health, Public rights, Attitudes, Social participation, Water quality, Drinking water, Potable water, Turbidity, Economic aspects, *Cost analysis, Expenditures.

The National Interim Primary Drinking Water Regulations, effective as of June, 1977, require that whenever a community water system fails to comply with any maximum contaminant levels established under the regulations, the water supplier must promptly publish notice of such failure in a newspaper of general circulation in the area serviced by the system or post notices in local post offices. Copies of the notice must also be furnished to local radio and television stations. This study examined maximum contaminant level violations for 164 water systems in 14 states to determine how the water systems notified their customers and how much it cost to do so. Putting an enclosure in the bill and sending a separate mailing are more frequently used than any other direct notification methods. The average cost of public notification for small systems was $31.30 for bacteriologic violations and $30.92 for turbidity violations. The average total cost for large systems reporting turbidity violations was $1218.58. For indirect notification, radio announcements, newspaper articles, and legal notices were all frequently used by the systems. Television stations carried the information as part of their news programs, and thus the water companies did not have to buy air time in this medium. In most cases it was felt that public notification was not effective in either educating or informing the public. Although some felt that consumers are generally indifferent to water problems, others expressed that it was unreasonable to expect customer support, given the delay between the violation and the notification. Concern was also noted that customers might not understand the notices and could in some cases become overly alarmed. (Baker-FRC)

Descriptors: *Assimilative capacity, *Waste load, *Water quality standards, Streamflow, Ouachita River, Louisiana, Model studies, Flow measurement, Low flow.

Steady-state models for estimating the assimilative capacities of stream segments can give overly conservative results under some circumstances. An example is a 161 km segment of the Ouachita River, Louisiana, in which the difference between the actual and predicted time-of-travel through the segment for the 7-day low flow was 86 days. Use of more complicated dynamic models can be avoided by using a graphical approach wherein low flow is determined intuitively by the intersection of two curves: the estimated travel time vs. Steady-state flow rate through the river segment and the frequency relationship between the 2 or 10 year low flow and the n-day flow averaging period used. In the Ouachita River segment the wasteload allocation computed by this method was 70% greater than by the previous method. (Cassar-FRC)

POISONS IN THE HUDSON,
C. S. Warren.
Clearwaters, Vol 10, No 2, p 12-13, June, 1980.

Descriptors: *Polychlorinated biphenyls, *Sediments, *Water pollution treatment, Hudson River, New York, Organic compounds, Chlorinated hydrocarbons, Rivers, Dredging, Legislation.

Although polychlorinated biphenyls (PCB) input to the Hudson River has been discontinued, river bed sediments remain highly contaminated. A plan to dredge 40 'hot spots' with average concentrations of 51-155 micrograms per g PCB has been developed. An estimated 1.8 million cu yards of material containing 277,600 pounds of PCB would be dredged and placed in a secure landfill built for this purpose. Total costs are estimated at $30 million for the 3-year project. Funds are not available at present to finance this cleanup. The EPA supports Superfund legislation as a means of implementing these plans. (Cassar-FRC)

Descriptors: *Zooplankton, *Lakes, *Electric fields, Water pollution effects, Lake Ladoga, USSR, Rotifers, Infusoria, Pulp and paper industry, Polarization, Eutrophication, Plankton.

The electric field and the distribution of zooplankton were studied on June 23, 1974, at 16 stations in Lake Ladoga, USSR, part of which was polluted with paper mill effluents. The electric field values were more negative in areas where rotifers and infusoria were more abundant. In unpolluted water the electric field was 5-10 times 10 to the minus 5th power V per m and the number of hydrobionts, 200 specimens per liter. Concentrations of 748 total plankton specimens per liter were found in water with electric field values of -1 to -1.2 times 10 to the minus 4th power V per m. The boundary zones between polluted and unpolluted water were rich in plankton. Two possible explanations for the difference in electric field gradient and the abundance of microorganisms were given. Eutrophication leads to an abundance of saprophytic bacteria which attract large numbers of zooplankton. On the other hand, electrostatic forces may attract charged microorganisms in the boundary zone between polluted and unpolluted water and hold them there until the gradient disappears as a result of dilution. OXYGENATION OF THE AVON RIVER,
Ontario Ministry of the Environment, Toronto.
D. Huber, D. Veal, and J. Goldman.
Water and Pollution Control, Vol 120, No 2, p 38-39, March/April, 1982.

Descriptors: River water, *Oxygenation, Rivers, Water quality, Aquatic plants, Respiration, Oxygen, Avon River, *Canada, Water quality management, *Aeration, *Instream aeration, Dissolved oxygen.

Water quality in the Avon River is affected by agricultural drainage and by urban inputs from the City of Stratford, Ontario, Canada. One major problem is low dissolved oxygen levels during summer night-time periods, resulting from the respiration of heavy growths of aquatic plants. An assessment was made of in-stream oxygenation of the river water. Oxygen was injected into the pumped water at a constant rate of 5.00 cubic meters per hour. With the 0.028 cubic meter/second flow of river water through the pumping system, the injected oxygen was estimated to have increased by oxygen concentration in the diffuser by 75 mg/liter. The estimated velocity of the river was 0.37 km/hr. Hence, it would take the river 10.8 hours to travel from the point of injection to an area 4.0 km downstream where the last dissolved oxygen monitor was located. Only localized benefits were obtained from this procedure because as the river moved on downstream, night time plant respiration would gradually offset the improvements of the oxygenation. After several

hours of travel away from the oxygenator, equating to about 1-3 river km, day-time conditions would result in natural oxygen recovery from plant photosynthesis. In order to substantially improve the night time oxygen status of a lengthy river, a number of oxygenation units would be needed. (Baker-FRC)

OPTIMAL LOCATION AND MANAGEMENT OF WASTE DISPOSAL FACILITIES AFFECTING GROUND WATER QUALITY,
Stanford Univ., CA. Dept. of Applied Earth Sciences.
S. M. Gorelick, and I. Remson.
Water Resources Bulletin, Vol 18, No 1, p 43-51, February, 1982. 7 Fig, 1 Tab, 25 Ref.

Descriptors: *Optimization, *Waste disposal, *Groundwater pollution, Water quality control, Simulation analysis, Numerical analysis, Solutes, Linear programming, Water supply, Aquifers, Groundwater management, Water pollution prevention, Path of pollutants.

Groundwater systems which are used for both waste disposal and water supply must be properly managed to ensure long range water quality protection. Numerical simulation of groundwater solute transport can be used in combination with linear programming to optimize waste disposal. Two management problems are described. In the first problem, waste disposal at potential sites is maximized while maintaining water quality at supply wells and operating an existing disposal facility. An iterative procedure is used to deal with changes in the velocity field induced by wastewater injection, which causes a nonlinearity in the solute transport equation. The value of parametric programming in analyzing waste disposal tradeoffs among existing and potential facilities is demonstrated. The second problem addresses the evaluation of a groundwater system in order to identify all sites which are suitable for subsurface waste disposal. This management model is manipulated so that the optimal values of the dual variables provide information with respect to the utility of each potential disposal site. The joint simulation and optimization approach permits optimal evaluation, selection, and management of groundwater waste disposal facilities where the aquifer is also used for water supply. DUAL OBJECTIVE CONTROL OF NUTRIENT LOADING INTO A LAKE,
Arizona Univ., Tucson. Dept. of Hydrology and Water Resources.
L. Duckstein, I. Bogardi, and L. David.
Water Resources Bulletin, Vol 18, No 1, p 21-26, February, 1982. 3 Fig, 6 Tab, 29 Ref.

Descriptors: *Nutrients, *Management planning, *Water pollution control, *Lakes, Eutrophication, Monte Carlo method, Multiobjective planning, Stochastic process, Phosphorus, Watershed management, Lake Balaton, Hungary, Model studies.

A framework is presented for multiobjective modelling of nutrient loading reduction from a watershed into a water body. Lake Balaton, Hungary, is used as a case study. The nutrient phosphorus was chosen for examination since it appears to be the limiting factor of eutrophication in this lake, which has experienced rapid development of tourism around the lake and of agriculture over the watershed. Although about 50% of the overall phosphorus loading originates from nonpoint sources, the mechanism is poorly understood and few observation data are available. While the objective of eutrophication control is to minimize phosphorus loading, the objective of watershed management is to maximize agricultural revenue. A discrete set of alternative methods for controlling nutrient loading is defined, which comprises a mix of control alternatives for the following elements: point sources, runoff, fertilizer type and application, cropping management, erosion, and sedimentation. A previously developed stochastic model is used to estimate the probability density function of dissolved and fixed phosphorus loading which reflects the control policy. A compromise solution can then be selected as a mix of the best-ranked policies. (Carroll-FRC)

AQUIFER MANAGEMENT IN DADE COUNTY,
Dade County Dept. of Environmental Resources Management, Miami, FL. Environmental Planning Div.
D. Yoder.
Water/Engineering and Management, Vol 129, No 4, p 34-38-40,42, April, 1982. 3 Fig, 4 Tab, 9 Ref.

Descriptors: *Aquifer management, *Land use, Dade County, *Florida, Biscayne Aquifer, Salt water intrusion, Organic compounds, Trihalomethanes, Chlorinated hydrocarbons, Pesticides, Wells, Groundwater pollution, Nitrates, Water management, Water quality control, Planning, Monitoring, Agriculture, Water supply, Nonstructural alternatives.

Early water management activities in Dade County, Florida, focused on drainage works. This lowered groundwater levels and allowed salt water intrusion into coastal aquifers. In 1975 the county Department of Environmental Resources Management (DERM) was designated the 208 areawide water quality planning agency. In 1979 the Biscayne Aquifer was named as a sole source aquifer as a result of studies undertaken by the DERM. The Department monitored nitrates in canals during and after storm events and in groundwater and found levels high, but not generally exceeding the 10 mg per liter standards. Sources of the nitrates were determined by monitoring at 26 selected sites for a year. The major contributor was, as expected, agriculture. A voluntary and educational control program is being developed to minimize the agricultural sources of nitrates. Volatile organics (trihalomethanes and industrial chemicals) are another concern. No pesticide contamination has been evident to date. Mean average volatile organics for all wells are 4.9 micrograms per liter in the wet season and 6.3 micrograms per liter in the dry season. An ordinance regulating land use around public water supply wells is being prepared. No new activities involving the use of hazardous materials would be permitted within the 210-day hydraulic travel time, which represents the highest recorded period without recharge from rainfall. Other agencies involved with water management in this region are the state Environmental Regulation Department, the South Florida Water Management District, and the U.S. EPA. Plans cited for development are new management practices for storm water disposal, improved septic tank regulations, a more active public information and education program, and expanded monitoring of water resources. THE SAFE DRINKING WATER ACT ON REVIEW,
Johnson (C. C.) and Associates, Inc., Silver Spring, MD.
C. C. Johnson, Jr.
Water/Engineering and Management, Vol 129, No 3, p 14-15, March, 1982. 1 Ref.

Descriptors: *Drinking water, *Legal aspects, Legislation, Safe Drinking Water Act, Public health, Water treatment, Regulations, Standards.

The legislative history of the Safe Drinking Water Act is reviewed as an aid to understanding several of the suggested changes in the legislation, since the authorizing legislation for the act will expire in September 1982. The major concern of some advocates for change is the discretion given to the Environmental Protection Agency to regulate drinking water contaminants which in the judgment of the administration may have an adverse effect on human health. Another issue under debate pertains to the administrator's authority to require a specific treatment technology. A third major concern of the public and suppliers is the economic impact of the Act on small water supplies. Many other issues have been raised in the debate over the Act, including subjects associated with public notification, health advisories, risk analysis, benefit-cost analysis, operation and maintenance regulations, and a host of others. LAW FOR ENVIRONMENTALISTS,
V. Sikora.
Journal of Environmental Health, Vol 44, No 5, p 258-259, March-April, 1982.

Descriptors: *Waste disposal, *Environmental protection, Permits, Hazardous materials, Legal aspects, Regulations, Sewage disposal.

Various problems in on-site sewage disposal are discussed, and an unusual way in which a county tried to resist the siting of a hazardous waste disposal facility is presented. Developments in administrative inspections in states are also cited. The problems presented deal with the denial of an on-site sewage disposal permit to a developer for his lots if they are unsuitable, even though there is no other use which can be made of the lots; the prohibiting of holding tank sewage disposal systems in coastal areas; the authority of a state health department to establish regulations for subsurface sewage disposal; and the justification for requiring permits to be obtained from different two state environmental agencies for an on-lot disposal system. THE NATIONAL INTERIM PRIMARY DRINKING WATER REGULATIONS, PART I - HISTORICAL DEVELOPMENT,
Northern Illinois Univ., DeKalb. School of Allied Health Professions.
W. A. Oleckno.
Journal of Environmental Health, Vol 44, No 5, p 236-239, March-April, 1982. 22 Ref.

Descriptors: *Drinking water, *Regulations, Potable water, Water quality, Standards, Legal aspects, Federal Jurisdiction, Public health, Water pollution.

This article is the first of a two part series dealing with the National Interim Primary Drinking Water Regulations as they apply to community water systems. The historical development of the Regulations is presented. They result from two nationally significant historical events: the promulgation and revision of the U.S. Public Health Service Drinking Water Standards of 1962 and the enactment of the Safe Drinking Water Act of 1974. These regulations were the first comprehensive set of drinking water standards applicable to all public water systems in the United States. It was the substandard condition of water supply systems in the United States as well as reports of suspected carcinogens in the New Orleans drinking water supply that underscored the need for the regulations and pro-

vided the motivation for their legislative mandates. In a February 1969 study, 41% of the water supply systems studied did not meet the limits established in the 1962 Drinking Water Standards; 56% were deficient in aspects of source protection, disinfection, clarification and/or pressure in the distribution system; 90% of the systems collected an insufficient number of bacteriological samples and/or collected samples showing poor bacteriological quality. While the Safe Drinking Water Act called for the eventual establishment of revised primary drinking water regulations after a detailed study of the health effects of contaminants in drinking water, no such standards have yet been proposed. (Baker-FRC)

THE NATIONAL INTERIM PRIMARY DRINKING WATER STANDARDS. PART II. IMPACT ON COMMUNITY WATER SYSTEMS. THE INDIANA EXPERIENCE,
Northern Illinois Univ., DeKalb. School of Allied Health Professions.
W. A. Oleckno.
Journal of Environmental Health, Vol 44, No 5, p 240-244, March-April, 1982. 3 Fig, 2 Tab, 14 Ref.

Descriptors: *Drinking water, *Standards, Water quality, Legal aspects, Legislation, *Indiana, Regulations, Federal Jurisdiction, National Interim Primary Drinking Water Regulations, Surveys.

The impact of the National Interim Primary Drinking Water Regulations (NIPDWR) on Community Water Systems (CWS) in Indiana was investigated. The current study was designed to determine to what degree the major provisions of the NIPDWR impacted on CWS in Indiana; how system size, source of water supply, and system ownership related to the reported impacts; and what steps had been taken or planned to reduce the major impacts. A total of 190 questionaires, representing 63.3% of those mailed, were returned. Of these, 4.7% were unusable. The final usable sample appeared to be reasonably representative of the population of Indiana CWS both geographically and in terms of relative percentages of CWS when stratified by system size, source of water supply, and system ownership, based on previous data. Based on the findings it would seem that the overwhelming majority of Indiana CWS experienced little or no impact from the NIPDWR. About 38% can be said to have experienced a moderate impact on system operations due to the passage of the NIPDWR. Classifying Indiana CWS by size, source of water supply, and ownership was of limited value in predicting the actual degree of impact of a singular provision of the regulations on a particular community water system. The classification schemes were useful in identifying important differences in system characteristics. (Baker-FRC)

PHOSPHORUS INACTIVATION BY ZIRCONIUM IN A EUTROPHIC POND,
Corvallis Environmental Research Lab., OR.
W. D. Sanville, C. F. Powers, G. S. Schuytema, F. S. Stay, and W. L. Lauer.
Journal of the Water Pollution Control Federation, Vol 54, No 5, p 434-443, May, 1982. 8 Fig, 7 Tab, 25 Ref.

Descriptors: *Phosphorus removal, *Zirconium, *Algae, Water treatment, Nutrients, Eutrophied lakes, Fish, Ponds, Phytoplankton, Sediments, Biomass.

Zirconium tetrachloride at initial levels of 5 mg Zr per liter controlled phytoplankton production in a euthrophic farm pond without producing acute or long-term effects in plants and animals. The chemical was added to the experimental half of the pond on March, 26-27, 1974. The other half, separated by a vinyl curtain, was the control. During the first year after treatment the experimental side had lower total phosphorus and all measures of biomass than the control. By the end of July the control pond contained 200,000 cells per ml, and the experimental side, 30,000 cells per ml. There was no drastic changes in species diversity in the experimental pond after Zr treatment. Zr contents of pond plants and invertebrates were highly variable. Fish showed no bioaccumulation. Total Zr concentrations (in mg per liter) in pond water were 1.9 the day after application, 0.592 on April 25, 1974, and 0.010 or less thereafter. Leakage from the experimental side to the control side caused Zr levels in the control side to reach 0.2 mg per liter for the month after application. Concentrations of Zr (micrograms per g) in sediments on November 20, 1975, were 468, experimental; 193, control; and 65 in an adjacent pond and fields. (Cassar-FRC)

LIMING FISH PONDS,
Auburn Univ., AL. Dept. of Fisheries and Allied Aquacultures.
C. E. Boyd.
Journal of Soil and Water conservation, Vol 37, No 2, p 86-88, March/April, 1982. 2 Tab, 30 Ref.

Descriptors: *Ponds, *Lime, Acidic water, Water treatment, Fish ponds, Carbonates, Fish food organisms, Sediments, Water quality management, Acid soils, Alkalinity, Calcium carbonate, Aquaculture.

Fish production in ponds can often be improved by liming with agricultural limestone, calcium hydroxide, calcium oxide, basic slag, or liquid lime. Properly applied, these materials react with acidity to form bicarbonate which is then available as a carbon source to plants. In sediments liming increases the rates of organic matter decomposition and nutrients cycling. Other effects of liming on ponds are reduction of turbidity and increase in production of fish food organisms. A table of lime requirements for pond muds of different pH and texture is given. Mud of pH < 4.0 requires 12,800 pounds per acre of $CaCO3$ in heavy loams or clays, 6,400 pounds per acre in sandy loams, and 4,000 pounds per acre in sand. Lime requirements drop to 1600, 1600, and zero, respectively, at pH 6.1-6.5. Ponds above pH 6.5 need not be limed. Application methods include liming the bottom with conventional spreader before filling, spreading from a boat or raft or platform between boats, and pumping slurries or blowing dust from a truck on the shore. The boats, and pumping slurries or blowing dust from a truck on the shore. The effects of lime treatment last 2-4 years if the water exchange rate is low. Highly acid ponds (below 4.5) usually received drainage from acid sulfate soils. For liming to be effective the source of acid must be treated or removed. (Cassar-FRC)

FUTURE WATER DEVELOPMENT POLICIES,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
G. V. Skogerboe, and G. E. Radosevich.
Water Supply and Management, Vol 6, No 1-2, p 221-232, 1982. 11 Ref.

Descriptors: *Salinity, *Colorado River, *Irrigation efficiency, *Water resources development, *Water policy, *River basin development, Desalination, Irrigation canals, Canal linings, Resources development, Water law, Water demand, Water management, Irrigation practices, River basins, Irrigation-return flow.

Energy resources are being increasingly developed in the Upper Colorado River Basin, with the consequences of further deterioration of the waters reaching the Lower Colorado Basin, especially in the form of added salinity. The basin-wide, nondegradation salinity policy for the lower stem of the river mandates that each development offset salinity contributions by making on-site improvements or off-site alterations somewhere else in the river basin. One practical off-site modification involves providing irrigation canal linings and on-farm improvements in irrigation efficiency. Such projects decrease irrigation diversion requirements while increasing agricultural productivity. with changes in western water laws, economic incentives and administrative programs could be devised to allow the contract sale or rent of decreased diversion requirements to other water demands; resulting revenues could be used to improve irrigation systems to further reduce salt loading to the Colorado River. (Geiger-FRC)

THE COLORADO RIVER SALINITY PROBLEM,
Environmental Protection Agency, Ada, OK. Robert S. Kerr Environmental Research Lab.
J. P. Law, Jr., and A. G. Hornsby.
Water Supply and Management, Vol 6, No 1-2, p 87-104, 1982. 5 Fig, 2 Tab, 29 Ref.

Descriptors: *Water quality control, *Salinity, *Colorado River, *Environmental effects, *Resources development, *Irrigation practices, River basins, River basin development, Water resources development, Resources management, Water demand, Irrigation water, Water management.

In the Upper Basin of the Colorado River, 52% of the salt loading comes from irrigated agriculture, 9% from natural point sources, and only 2% from municipal and industrial uses. Damage from salt loading occurs mostly in the Lower Colorado River Basin. Remedies for salinity problems include collecting and treating or disposal of natural point sources. Cost-effective technologies for dealing with salt loadings due to irrigated agriculture include improved irrigation and on-farm management practices to reduce deep percoaltion loss and the building of canals and laterals to channel salt losses. Development of coal and oil shale resources in the Upper Colorado River Basin will necessitate use of river water, allowing even less downstream flow for salt dilution. Future water resource developments will require more stringent salinity control and management decisions based on scientific reasoning rathe than political motivations. (Geiger-FRC)

INTERNATIONAL PROBLEMS ON THE COLORADO RIVER,
Colorado River Board of California, Los Angeles.
M. B. Holburt.
Water Supply and Management, Vol 6, No 1-2, p 105-114, 1982. 1 Tab.

Descriptors: *Water quality control, *Salinity, *Colorado River, *International agreements, *Irrigation effects, River basins, Water policy, Water management, Groundwater availability, Water resources development, Desalination.

The Colorado River provides irrigation water to nearly 500,000 acres of land in the Republic of Mexico and serves over 500,000 people in that country. In 1961, the discharge of highly saline pumped drainage from the Wellton-Mohawk Irrigation and Drainage District surrounding Yuma, Arizona, significantly increased the salinity of the Colorado River waters reaching Mexico. In 1973, a Water Treaty was signed, establishing definite limits to the salinity levels that would be allowed in the Colorado River was delivered to Mexico upstream from the Morelas Dam in relation to the water at Imperiam Dam. Although this treaty was intended as a permanent solution to the salinity problem, new arguments could arise with Mexico if the operation of the Unuma Desalting Plant fails to reach the standards which were agreed upon. The pumping of groundwater by Mexico that induces groundwater flow from the United States to Mexico may also develop into a controversial issue. New water resources developments in the United States may require the implementation of additional salinity control measures in the near future. (Geiger-FRC)

OPTIMAL SALINITY CONTROL PROGRAM FOR THE UPPER COLORADO RIVER BASIN,
Agricultural Research Service, Prosser, WA. Irrigated Agriculture Research and Extension Center.
R. G. Evans, W. R. Walker, and G. V. Skogerboe.
Water Supply and Management, Vol 6, No 1-2, p 169-197, 1982. 14 Fig, 7 Tab, 13 Ref.

Descriptors: *Model studies, *Optimum development plans, *Desalination, *Cost analysis, *Colora-

do River, Salinity, Optimization, Irrigation efficiency, Planning, Irrigation effects, River basin development, Water resources development, Irrigation-return flows.

A simple multi-level nonlinear optimization model was used to derive the most cost-effective strategies for salinity control in the waters of the Upper Colorado River Basin. The methodology gives qualitative data on the location and general types of alternatives that would be useful in a least cost basin-wide salinity control program and the expected salt load reduction and annual costs of each preselected level of control. Conditions from January 1980 were used to estimate the costs and salinity contributions associated with various control alternatives. Cost effectiveness functions were formulated for each major irrigation canal and laterals, aggregate laterals under each canal, and on-farm improvements for each agricultural project area. Similar functions were developed for such point sources as Paradox Valley, Glenwood-Dotsero Springs and Crystal Geyser. The desalination of agricultural return flows was also evaluated. The optimal salinity control program in the Upper Colorado river Basin would cost about $30 million annually for 1.2 million metric tons of salt removal. Sensitivity analysis of the optimization procedure showed that substantial error in costs and the respective salt load contributions of the individual alternatives would have to occur to alter the optimal order of implementation of a basin-wide salinity control program. 6. WATER RESOURCES PLANNING

6A. Techniques Of Planning

WATER REUSE PLANNING BY MEANS OF AN INPUT-OUTPUT TABLE,
Swiss Reinsurance Co., Zurich.
D. Klooz, and D. W. Hendricks.
Journal of the American Water Works Association, Vol 74, No 1, p 51-56, 1982. 7 Fig, 3 Tab, 3 Ref.

Descriptors: Planning, *Water reuse, *Colorado, *Cache La Poudre River Basin, Data analysis, *Project planning, Agricultural water use, Industrial water, Water storage, *Input-output analysis, Water demand, Water use, Future planning, Used water.

An input-output table analysis suitable for application in water reuse planning was developed and applied to the Cache La Poudre River basin in Colorado. Analysis is facilitated by the ability of the input-output table to organize and collate large amounts of complex data both structurally and operationally. Aggregated input-output tables were developed for proposals for new projects construction and intensified reuse for the year 2020. The tables failitate comparison of the uses of virgin water and used water between the two solutions. Reused water is shown to represent a feasibile means for meeting projected demands. The reuse factor, defined as the total water use divided by the total amount of virgin water supply, increases from 1.34 to 1.46 upon implementation of intensified reuse. Used water is prominent in satisfying industrial and agricultural water demands under the intensified reuse solution. Unplanned reuse maintains its important place in both solutions. Basin outflow is reduced by intensified reuse. The amount of water saved by intensified reuse is only about 8%, but this could spare the need for expensive new storage projects. This clearly organized evaluation format aids in assessing proposed projects for their ability to satisfy new water demands and in examining their positive and negative interactions on the rest of the system. (Carroll-FRC)

AN EVALUATION OF THE URBAN DESIGN STORM CONCEPT,
Illinois Univ. at Urbana-Champaign. Dept. of Civil Engineering.
H. G. Wenzel, Jr., and M. L. Voorhees.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220666, Price codes: A08 in paper copy, A01 in microfiche. Research Report No 164, 147 p, 43 Fig, 19 Tab, 25 Ref, 8 Append. OWRT-A-095-ILL(2). 14-31-0001-6073.

Descriptors: *Design storms, *Simulation model, *Storm sewers, *Urban drainage, *Urban runoff, Design-hydraulics, Frequency analysis, Sewer systems, Simulation analyses, Storm drainage, Design flow.

This report describes an evaluation of the assumption commonly employed in drainage design that the return period of the rainfall used to design a system is the same as the peak flow produced by that rainfall. Specifically, the sensitivity of the frequency response of four catchments to design storm parameters is examined. Parameters include, hyetograph shape, antecedent soil moisture and rainfall duration. A continuous simulation model is used to compute simulated historical frequency responses for three different long term rainfall records.. Design storms also developed from depth-duration-frequency analyses of the rainfall data. Comparisons are made on frequency graphs. It is concluded that an appropriate choice of design storm parameters can produce a design which yields peak flows of the desired return period.

A SCREENING MODEL TO QUANTIFY RESILIENCE,
Harvard Univ., Cambridge, MA.
M. B. Fiering.
Water Resources Research, Vol 18, No 1, p 27-32, February, 1982. 5 Fig, 2 Tab, 7 Ref.

Descriptors: *Performance evaluation, *Water resources development, *Risks, Planning, Resiliency, Costs, Economic evaluation, Systems analysis, Water supply, Optimization, *Project planning, Design criteria, Reservoirs, *Model studies.

The concept of resilience, used in statistics and biology, is applied to water resource systems. A resilient water supply system does not respond precipitously to a major surprise or perturbation during the course of its economic life. For example, a well-designed water system is relatively insensitive (or resilient) to an event such as the Northeast Drought of 1961-65. Neglecting this resilience factor in planning an optimum design may produce a system which is cost-effective but intolerant of perturbations. A screening model is presented for 8 reservoirs of different size operating in parallel. Results imply that large systems which are not markedly over- or understressed can adapt to a range of potential capital investments without seriously compromising performance characteristics. For understressed systems the most resilient design used 2 or 3 reservoirs; for overstressed systems, more than 6; and for the intermmediate cases, 4. Another measure of system resilience is based on adaptability of a single design to changes in target. A fully resilient system can deliver all intermediate targets at the same performance level. Mean resilience peaks at systems slightly smaller than maximal. Further increases in size produce small reductions in mean resilience and greatly reduce variance (resilience). A tradeoff between the mean and standard deviation of resilience can help attain the optimum system size. (Cassar-FRC)
W82-05044

ALTERNATIVE INDICES OF RESILIENCE,
Harvard Univ., Cambridge, MA.
M. B. Fiering.
Water Resources Research, Vol 18, No 1, p 33-39, February, 1982. 3 Fig, 4 Tab, 9 Ref.

Descriptors: *Performance evaluation, *Water resources development, *Risks, Planning, *Resilience, Economic evaluation, *Systems analysis, *Project planning.

The concept of resilience, previously introduced into ecology literature, may be useful in the application of systems analysis to water resources planning. Various ideas regarding resilience deal with recovery of water resource systems and minimization of surprises. Several mathematical definitions for resilience of water resource systems are outlined, and the advantages and disadvantages of these definitions compared. No single definition is designated as the best. All are based on the time required to pass from one system state to another. The passage to or from a given state is defined as failure. Some of the definitions involve probability of recovery from failure to an acceptable state within a specified time interval. (Cassar-FRC)
W82-05045

ESTIMATES OF RESILIENCE INDICES BY SIMULATION,
Harvard Univ., Cambridge, MA.
M. B. Fiering.
Water Resources Research, Vol 18, No 1, p 41-50, February, 1982. 5 Fig, 2 Tab, 3 Ref.

Descriptors: *Reservoirs, *Design criteria, Planning, *Water resources development, *Model studies, Mathematical studies, *Resilience, Alternative planning, Reservoirs.

A simulation study was performed to define and assess the basin property of resilience. Testing was carried out on a few speculative definitions developed for this property. The purpose of the analysis was to develop some insights into the resilience of the system in the vicinity of its global or local cost optima. Resilience indices were calculated according to some of the previously published formulas for several reservoir configurations which constitute a set of sample plans for a river basin. Basin characteristics are introduced to estimate proposed surrogates of system resilience without the necessity of performing long and expensive simulation studies. These simulations are necessary to develop resilience indices for the sample basins and to compare them to a few conventional ranking functions. The objective of this procedure was to determine if conventional indices replicate information contained in resilience indices and the extent to which either or both of these can be estimated from basin geometry. Consideration is given to combinatorial analysis, system operating policy, generalization to six reservoir storages, and an index for estimating system performance. The results, although imperfect, are encouraging and suggest areas for continuing work in the mapping of basin characteristics and configuration into performance indices. (Carroll-FRC)
W82-05046

ESTIMATING RESILIENCE BY CANONICAL ANALYSIS,
Harvard Univ., Cambridge, MA.
M. B. Fiering.
Water Resources Research, Vol 18, No 1, p 51-57, February, 1982. 3 Fig, 6 Tab, 4 Ref.

Descriptors: *Planning, *Reservoirs, *Mathematical studies, Design criteria, *Model studies, Operating criteria, *Water resources development, *Resilience, Alternative planning.

In a previous study, mutivariate or cluster analyses were proposed to define the basin properties and storage surrogates which, alone or in combination, could be used to form a tight estimator of system performance. Canonical correlation was suggested as especially suitable for predicting system resilience and some conventional performance indices without expensive simulation, and thus 'backing into' an operational definition of resilience. Canonical correlation analysis is used to formulate linear estimates of independent or orthogonal (incremental) information on the performance of water resource systems. Simple economic and resilience indicators are compared, and for the particular configurations selected the replicated and inde-

LIBRARY U. OF ILL. URBANA-CHAMPAIGN

pendent information sets are explained in terms of the connectivity of the various reservoirs. The canonical correlations obtained are relatively high, suggesting that there is a significant replication of information. A taxonomy is developed which suggests the basin and structural characteristics which would show less replication and permit improved description of system performance. (Carroll-FRC)

USE OF MATHEMATICAL MODELS TO GENERATE ALTERNATIVE SOLUTIONS TO WATER RESOURCES PLANNING PROBLEMS,
Illinois Univ. at Urbana-Champaign. Dept. of Civil Engineering.
S. Y. Chang, E. D. Brill, Jr., and L. D. Hopkins.
Water Resources Research, Vol 18, No 1, p 58-64, February, 1982. 5 Fig, 3 Tab, 19 Ref.

Descriptors: *Alternative planning, *Optimization, *Model studies, Mathematical models, Wastewater treatment, *Water resources development, *Wastewater facilities.

Alternatives for water resources planning problems were generated by three optimization models, the Hop. Skip, and Jump method (HSJ), a random method, and a branch and bound/screening method (BBS). The sample problem was to find the best arrangement for a wastewater treatment system with 15 wastewater sources, 12 possible plant sites, and 15 potential interceptor levels. The sets of alternatives generated by all 3 methods were different from each other. For each method the alternatives were different in different ways. The HSJ method generated alternatives differing in number of plants, i.e., degree of centralization. The random method produced alternatives with similar numbers of plants and interceptors but with facilities in different locations. The BBS method generated alternatives in which part of the wastewater system was constant but combined with other arrangements of the rest of the system. The wide range of alternatives offers possibilities for creative solutions and consideration of political, social, and environmental aspects by the evaluators. All methods were efficient, suggesting that in practice it might be desirable to use all 3 for formulating alternatives. (Cassar-FRC)

ROBUSTNESS OF WATER RESOURCES SYSTEMS,
International Inst. for Applied Systems Analysis, Laxenburg (Austria).
T. Hashimoto, D. P. Loucks, and J. R. Stedinger.
Water Resources Research, Vol 18, No 1, p 21-26, February, 1982. 5 Fig, 4 Tab, 13 Ref.

Descriptors: *Performance evaluation, *Economic evaluation, *Water resources development, Design criteria, Robustness, Planning, Alternative planning, Costs, *Skane, *Sweden, Systems analysis, Water supply, Optimization, Risks, Project planning, *Cost analysis.

Robustness describes the overall economic performance of a water resource project. It measures the likelihood that the actual costs of a project will not exceed some fraction of the minimum possible cost of a system designed for the actual conditions that occur in the future. A water supply system planning problem in Skane, Sweden, was used as an illustration of the method. A large-scale interbasin transfer was proposed to meet uncertain future demands. Four design alternatives were evaluated for ability to meet demand in the year 2000. The value of robustness was calculated for each alternative. One of the four possibilities was clearly more robust than the other three, giving only a 2% probability of relatively very poor cost performance. (Cassar-FRC)

RELIABILITY, RESILIENCY, AND VULNERABILITY CRITERIA FOR WATER RESOURCE SYSTEM PERFORMANCE EVALUATION,
International Inst. for Applied Systems Analysis, Laxenburg (Austria).
T. Hashimoto, J. R. Stedinger, and D. P. Loucks.
Water Resources Research, Vol 18, No 1, p 14-20, February, 1982. 9 Fig, 2 Tab, 26 Ref.

Descriptors: *Performance evaluation, *Water resources development, *Risks, Reliability, Resiliency, Vulnerability, Dam failure, *Reservoirs, Operating policies, Systems analysis, Reservoir releases, Water supply, Planning.

Three performance criteria for evaluating water resource systems are proposed as additions to the commonly used mean and variance of benefits, pollutant concentrations, and operating variables. These are reliability (how likely a system is to fail), resiliency (how quickly it recovers from failure), and vulnerability (how severe are the consequences of failure). The three criteria are expecially important during periods of drought, peak demand, or extreme weather. As an example, they are used to evaluate the performance of a water supply reservoir under a winter operating policy of a specified released with storage of the excess. Alternative summer policies are standard (meet as much demand as possible), hedging (providing a portion of the target release), and one in which the entire target is met if possible, but in case of unavoidable modest failure no water is released. In this system high reliability is accompanied by high vulnerability. Although the optimum situation is maximum reliability and minimum vulnerability, this is impossible in practice. Tradeoffs can produce a high reliability, modest resiliency, and low vulnerability. (Cassar-FRC)

MODELLING AND CONTROL OF DISSOLVED OXYGEN IN AN ESTUARY,
Ahmadu Bello Univ., Zaria (Nigeria). Dept. of Electrical Engineering.
B. J. Olufeagba, and R. H. Flake.
Ecological Modelling, Vol 14, No 1, p 79-94, 1981. 9 Fig, 3 Tab, 13 Ref.

Descriptors: *Dissolved oxygen, *Estuarine environment, *Mathematical models, Nitrification, Water pollution control, Bays, Prediction, Biochemical oxygen demand, Algorithms, Water quality management, Management planning, *Jamaica Bay, *New York.

Jamaica Bay, New York, is a highly polluted estuary which suffers from reduced dissolved oxygen concentrations due to the biochemical oxygen demand (BOD) of organic materials discharged by waste sources. The two-dimensional spatial distribution of dissolved oxygen in Jamaica Bay is approximated by a vector multipoint boundary value problem. This problem, which includes interactions involving the carbonaceous BOD and the total unoxidized nitrogen, is solved by a multiple shooting technique. This shooting algorithm requires less computer storage than its finite difference counterpart, realizes higher order accuracy easily, and requires the solution of a relatively small matrix. These results are then used in a variational sensitivity model, which is used together with the Goldfarb method for constrained nonlinear programming to determine optimal management policies. The performance index in each case is the capital cost of nitrification treatment at each of the polluting sources discharging into the bay. The model is used to determine the optimal economic nitrification treatment levels required to achieve a minimum dissolved oxygen concentration level of 5 milligrams per liter throughout the bay. The use of this model for the evaluation and choice of management alternatives in water quality planning is demonstrated. (Carroll-FRC)

RANDOM DIFFERENTIAL EQUATIONS IN RIVER WATER QUALITY MODELING,
Humboldt State Univ., Arcata, Dept. of Engineering.
B. A. Finney, D. S. Bowler, and M. P. Windham.
Water Resources Research, Vol 18, No 1, p 122-134, February, 1982. 11 Fig, 8 Tab, 31 Ref.

Descriptors: *Water quality, *Rivers, *Stochastic processes, *Model studies, Biological oxygen demand, Dissolved oxygen, Probablistic process, *Fate of pollutents.

A random differential equation model, a development from steady state probabilistic river water quality models, compensates for uncertainties such as natural variability and uncertainties in measurement--unrepresentativeness, errors, and incompleteness. The model is not limited by Monte Carlo, first-order analysis, or estimation theory techniques. Equations describing the water quality system are transformed from deterministic to random differential equations. Solution of these equations allows prediction of the joint probability density function of the water quality constituents at any location in the river system. Point loads and diversions may be handled. The model was applied to a sensitivity problem and to determination of BOD and dissolved oxygen in a hypothetical river system. Representing the randomness in water quality equations inputs and coefficients as a Gaussian white noise process is convenient. Randomness in water quality coefficient equations has greater influence on prediction concentrations than randomness in equation inputs. It is advantageous to approximate the marginal probability distribution function of BOD and dissolved oxygen with a normal distribution. This model may be useful in design of river water quality monitoring systems, implementation of reliability based on stream standards, and quantification of variability of constituent concentration for mangement, planning, and control purposes. OPERATIONAL RESEARCH TECHNIQUES IN RIVER BASIN MANAGEMENT,
Waterloo Univ. (Ontario). Dept. of Systems Design Engineering.
K. W. Hipel.
Canadian Water Resources Journal, Vol 6, No 4, p 205-226, 1981. 1 Fig, 2 Tab, 51 Ref.

Descriptors: *Decision making, *Operations research, *Water management, *River basins, Conflict analysis, Fuzzy set theory, Model studies, Social aspects, Multipurpose projects, Poplar River, *Saskatchewan, Fort Peck, Montana, Stability analysis, Water resources development, Systems analysis, Canada.

Operations research methods for use in river basins management are described. The quantitative methods, divided into deterministic and probabilistic categories, have been widely applied to management problems. Nonquantitative methods, including the fuzzy set theory combined with multicriteria modelling, are especially valuable in evaluating intangible factors such as social and cultural effects of a water project. A conflict analysis methodology, the improved metagame analysis algorithm, is applied to the conflict in the Poplar River Basin (Saskatchewan-Montana). The three conflicting players are the Saskatchewan Power Company's thermal generating station, completed in 1979; Fort Peck Indians' irrigation water; and the International Joint Commissions's interests. Options are the possible activities of the players, such as power plant or irrigation projects of different sizes. Of the 4048 possible outcomes in this situation, only 22 are feasible. These are arranged in order of preference for each party. Each feasible outcome is then subjected to stability analysis by the improved metagame method, and equilibria (three in this study) established to indicate options most satisfactory to all parties. COMPUTER-AIDED EVALUATION OF PERU'S HYDROPOWER,
S. Morariu.
International Water Power and Dam Construction, Vol 33, No 12, p 52-55, December, 1981. 2 Fig, 2 Tab.

Descriptors: *Computer programs, *Hydroelectric power, Predictions, Hydrologic data, Hydroelectric powerplants, Peru, Water resources development, Future planning.

A master plan has been prepared for the development of Peru's hydroelectric potential. As a first step in this process, data on the hydrological characteristics of Peru were collected from limited published sources, including Landsat data and radar photographs, and backed up by field surveys. A unified, computerized hydrological data bank for Peru is now in existence. A computerized model of 111 river basin models was used to calculate the mean discharge and theoretical hydro potential and to define 81,355 kilometers of hydrographic networks. The theoretical mean linear hydropower potential for Peru was found to be about 206,107 megawatts, most of which is concentrated on the eastern side of the Andes. About 25 to 50% of this quantity could be developed within existing technical and economic constraints. Potential projects were identified on the basis of available topographical, geological, and hydrological information and then inspected to evaluate technical feasibility. Basic designs were developed for all projects considered to be technically feasible. General cost curves were applied to each project and project variation for the estimation of capital expenditures attributable to each project element. Potential hydroelectric projects were then compared on the basis of calculated unit cost per kilowatt hour of energy produced. A preliminary screening process was conducted to identify optimal development chains on the basis of the minimum weighted cost of energy production. Potential projects were then ranked according to a number of technical/economic criteria and classified with respect to a range of installed capacities and availability of basic information. Visits to over 800 sites resulted in assessment of 560 projects in 2,300 different configurations. (Carroll-FRC)

APPLICATIONS OF SIMULATION TO SPECIFIC WATER PROJECTS,
Bochum Univ. (Germany, F.R.). Dept. of Water Sciences and Environmental Technology.
R. Harboe, and G. A. Schultz.
Journal of Hydrology, Vol 51, No 1-4, p 131-138, May, 1981. 6 Fig, 10 Ref.

Descriptors: *Simulation analysis, *Water supply development, *Water use, Water pollution, Irrigation, Environmental effects, Mathematical models, Water management, Computer programs.

Digital computer simulation involves the reproduction of the real system's static and dynamic characteristics through a mathematical model which is translated into a computer program. In only a few minutes this model can then reproduce the behavior of the system over long periods of time, allowing the decision-maker to analyze several alternatives rapidly. In water resources systems, computer simulations may be used to examine such alternatives as different sizes of reservoirs, power plants, and irrigation areas; several operation policy options; and hydrological records and various constraints due to water quality, navigation, recreation, and/or environmental protection. Four examples of applications of simulation analysis are discussed. These include simulations for a hydroelectric power system in Central Europe, for an irrigation system in South America, for a water supply reservoir system including environmental requirements in Germany. The examples include discussion of inputs used for each of the simulations, analysis goals, and performance of the simulation. The examples demonstrate the flexibility of the simulation technique. The technique is not too difficult to apply in practice and can be used to find optimum solutions for both design and operation of water resources systems. (Carroll-FRC)

THE ROLE OF UNCONDITIONED AND CONDITIONED CUMULATIVE DISTRIBUTION FUNCTIONS IN RESERVOIR RELIABILITY PROGRAMMING,
Institut za Vodoprivredu Jaroslav Cerni, Belgrade (Yugoslavia).
S. P. Simonovic, and M. A. Marino.
Journal of Hydrology, Vol 52, No 3/4, p 219-228, July, 1981. 5 Tab, 14 Ref.

Descriptors: *Reservoir operation, *Mathematical studies, *Computer models, Reservoir releases, Reservoir design, Stochastic process, Mathematical models.

Mathematical models based on the relliability programming technique have been developed for solving stochastic problems of reservoir design and/or operation. The results obtained from the reliability program of a reservoir management problem based on the use of unconditioned cumulative distribution functions are compared with those obtained when conditioned cumulative distribution functions are used. The reliability program considers the reservoir releases and the reliabilities of the elements of the reservoir system as decision variables. Data from the Vardar River system in Yugoslavia are fitted with Pearson Type-III distributions for the case of unconditioned cumulative distribution functions and with bivariate gamma distributions for the case of conditioned cumulative distribution functions. Objective-function values and reliability tolerances obtained when conditioned cumulative distribution functions were used in the reliability program were greater than those obtained using unconditioned cumulative distribution functions. Although the study results cannot be generalized to other reservoir management problems, the use of conditioned cumulative distribution functions will give more realistic results than the use of unconditioned cumulative distribution functions in cases in which streamflow data are known to be stochastically dependent. It is concluded that the use of conditioned cumulative distribution functions represents a step forward in overcoming the conservative nature of stochastic models used for the design and/or operation of multipurpose multiple reservoir systems. DISCRETIZATION IN STOCHASTIC RESERVOIR THEORY WITH MARKOVIAN INFLOWS,
Monash Univ., Clayton (Australia). Dept. of Mathematics.
R. M. Phatarfod, and R. Srikanthan.
Journal of Hydrology, Vol 52, No 3/4, p 199-218, July, 1981. 9 Tab, 8 Ref.

Descriptors: *Stochastic process, *Mathematical models, *Reservoirs, Mathematical equations, Markov process, Numerical analysis.

The twin problems of the nature of discretization and the size of the unit of discretization used in stochastic reservoir theory are examined. The feasibility of constructing a discretization sheme which allows the relese and the reservoir size to assume fractional values is demonstrated. The case where the inflows form a sequence of seasonal Markov dependent variables is then considered. A discretization scheme is suggested which gives better estimates of the probabilities of emptiness and fullness of the reservoir than those provided by the scheme developed by Dearlove and Harris. A numerical comparison of these probabilities with those obtained by simulation is made for the case where the inflows follow a Thomas-Fiering model. Finally, the effect of the size of the unit of water on these probabilities is disussed briefly. (Carroll-FRC)

OPTIMALITY, INFORMATION GENERATION STRATEGIES, AND WATER RESOURCES MANAGEMENT IN THE YUKON TERRITORY,
British Columbia Univ., Vancouver. Westwater Research Center.
I. K. Fox.
Canadian Water Resources Journal, Vol 5, No 3, p 56-68, 1980. 1 Fig, 3 Tab.

Descriptors: *Water management, *Project planning, *Research priorities, Planning, Yukon Territory, Public participation, Westwater Project, Electric power, River basins, Optimization.

The planning method used in the Westwater Research Center's Yukon Water Research Program (University of British Columbia) is described. Basic steps are as follows: (1) determine the range of preferences through interviews with persons representing many interest groups, (2) establish investigation priorities during a 3-day professional workshop divided into four groups (electric power, mining, fish and wildlife, and recreation-tourism), (3) undertake the high priority investigations, (4) assess the study results at a second workshop, and (5) prepare reports. Two suggestions are emphasized: (1) the public should be included in establishing investigation priorities, and (2) yearly review and reporting produces results more sensitive to changes in economic, social, and environmental conditions than final reports after several years' study. (Cassar-FRC)

EVOLUTION OF WATER MANAGEMENT TECHNIQUES,
British Columbia Univ., Vancouver. Dept. of Civil Engineerig.
S. O. Russell.
Canadian Water Resources Journal, Vol 5, No 3, p 49-55, 1980. 3 Ref.

Descriptors: *Decision making, *Water management, *Computers, Simulation analysis, Hydrologic data collections, Data collections.

Computers have aided the evolution of water management techniques during the last 20 years. Storage and manipulation of hydrologic data and simulation analysis of runoff and floods are widely and successfully used in decision making. However, human judgment has not been eliminated, only used at a different level and time. Examples of simulation analysis are forecasting levels in Lake Athabasca if the Peace River Project is built and optimizing design of water distribution networks. Although problems involvig uncertainty and multiple objectives are still difficult to handle, the trend is toward more objective and automatic techniques and less judgment and intuition. (Cassar-FRC)

AN APPLICATION OF MATHEMATICAL PROGRAMMING TO WATER RESOURCES PLANNING: AN ECONOMIC VIEW,
New Hampshire Univ., Durham. Inst. of Natural and Environmental Resources.
B. E. Lindsay, and D. L. Dunn.
Water Resources Bulletin, Vol 18, No 2, p 289-296, April, 1982. 6 Tab, 4 Ref.

Descriptors: *Optimization, *Water resources development, Systems analysis, *Regional planning, Planning, Water use, Water demand, Water supply, Municipal water, Mathematical models, Model studies, Merrimack River, New Hampshire, Costs, Water distribution.

A mixed integer multiperiod programming model using hydrologic and economic data was used to identify the discounted least cost of water supply, distribution, and scheduling for three New Hampshire towns, Hudson, Merrimack, and Nashua. The model was applied on an individual town basis and on a regional basis. Costs of regionalized water resources development ($2.8-4.3 million) were about 5-10% less than costs of deregionalized schemes for the three towns ($3-4.5 million) for present water usage, 20% more water usage, and 10% less water usage. FLOOD DAMAGE ASSESSMENT AND FLOOD CONTROL PLANNING AS PART AND PARCEL OF THE ECONOMICS OF WATER UTILIZATION (VLOEDSKADEBEPALING EN VLOEDSKADEBEHEER AS ONDERDELE VAN DIE EKONOMIE VAN WATERBENUTTING),
Orange Free State Univ., Bloemfontein (South Africa).
M. F. Viljoen, and D. J. G. Smith.
Water S. A., Vol 8, No 1, p 45-51, January, 1982. 9 Fig, 12 Ref. English abstract.

Descriptors: *Economic aspects, *Flood control, Floods, Flood damage, Flood protection, Cost-benefit analysis, Cost analysis, Water use, Planning.

In the field of the economics of water utilization, flood damage assessment and flood control planning play integral parts. National welfare is increased by rational use of national resources, including water. Welfare economics supplies the theoretical framework for use in the planning of water utilization. The cost-benefit technique is generally accepted as the application of welfare economics, but it is necessary to consider that this technique only focuses on economic efficiency within a partial equilibrium framework. The traditional application of the technique does not supply the final answer for the maximization of welfare. For completeness, this method should be supplemented with the evaluation of other welfare objectives such as environmental quality, distribution of income and security. In planning for control of flood damage, the minimization of flood damage represents the greatest part of the benefits to be obtained, and thus it comprises one of the important components in cost benefit analysis. Other benefits embodied in welfare objectives are frequently hard to measure, and the best alternative seems to be an optimal understanding of these, quantitatively and qualitatively. When weighing the intangibles against the tangibles, value judgments will necessarily have a role to play. (Baker-FRC)

COMPUTER-AIDED EVALUATION OF PERU'S HYDROPOWER,
S. Morariu.
International Water Power and Dam Construction, Vol 34, No 1 p 34-39, January, 1982.

Descriptors: *Hydroelectric plants, *Evaluation, Computers, Testing procedures, Hydrology, Geology, *Turbines, Flow profiles, Hydraulics, Water demand, *Peru.

The kind of data and the assessment of the data employed in a computer aided study of Peru's hydropower situation are presented. Both geologic and hydrologic parameters were included in the study. The overall objective of the hydrology studies was the analysis of all available data and the identification of regional patterns and trends. The hydrological parameter of overriding importance was the flow available for the turbines. Design floods were estimated through regional analysis. A regional drought analysis was also carried out, based on the need to determine the firm capacity of the independent projects and the guaranteed power and energy of the interconnected system. A very large number of hydropower projects was evaluated using a computer based method which allowed a systematic evaluation of the hydropower resources of the country to be made. With over 2300 hydropower project options, it was possible to analyze 1.6 x 10 to the 13th power river development chains. As a result of the optimization model used, 328 project variations emerged as being compatible, with a total installed capacity of over 58,000 MW. It is suggested that a proper and systematic evaluation of the world's hydropower be made using the same or similar computer aided methodologies to minimize the time and manpower requirements without sacrificing accuracy. INSTITUTIONAL OBSTACLES TO WATER REUSE IN THE WESTERN UNITED STATES,
Dornbusch (David M.) and Co., Inc., San Francisco, CA.
K. Wehbring.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220641, Price codes: A09 in paper copy, A01 in microfiche. OWRT/RU-80/8, 1981, 195 p, 7 Fig, 3 Tab. OWRT C-80215-R(1). 14-34-0001-8819.

Descriptors: *Water reuse, *Institutional constraints, *Legal aspects, *Political aspects, Local governments, Water law, Water rights, Economic aspects, Financing, Public health, Wastewater treatment, Planning, City planning, *Western United States, California, Arizona, Nevada, Colorado, New Mexico.

The institutional barriers were examined to reusing wastewater in nine communities in the Western United States. Institutional barriers include legal, political, financial and organizational problems which hinder the development of water reuse projects. Case studies were prepared for the following communities: Santa Clara Valley Water District, Goleta County Water District, Los Angeles, Las Virgenes, and Solano County in California; Tucson, Arizona; Las Vegas, Nevada; Northglenn, Colorado; and Santa Fe, New Mexico. The study identifies obstacles and suggests ways of overcoming the obstacles. They are 1) Competing uses for water; 2) EPA grant requirements; 3) Health regulations; 4) Financing methods; 5) Neighborhood opposition to treatment facility site; 6) Urban growth issues; 7) Inter-agency conflict. The main approach recommended for overcoming these obstacles is to carry out institutional planning as a part of the overall planning for a water reuse project so that obstacles can be defined and alternative methods of overcoming them devised.

WATER AND WASTEWATER MANAGERS FACE THE FINANCIALLY TROUBLED 1980S,
Graham Associates, Inc., Dallas, TX.
F. G. Honeycutt, Jr., and W. B. London.
Water/Engineering and Management, Vol 129, No 2, p 24-26, February, 1982. 2 Tab.

Descriptors: *Economic aspects, *Water management, Planning, Wastewater treatment, Feasibility studies, Municipal wastewater, *Wastewater management, Future planning.

Many water managers believe that financing will be the major problem facing the water industry in the current decade. The water industry is striving to meet this problem through reassessments of its management and financial practices in an effort to become self-reliant in performing the needed capital improvements. In the preparation of budget controls and financing alternatives for capital improvement programs, some of the major economic factors include current and projected inflation as well as municipal bond and prime interest rates. Inflation is the primary economic factor that continually plagues budgets and long term financial plans. Water and wastewater managers are especially aware of the effect of inflation on municipal bond and prime interest rates. However, in spite of the current hardships facing water and wastewater managers, innovative and creative capital improvements strategies are either currently available or are in the formulation stages. Several methods of direct state participation are currently in use throughout various parts of the country. A concept also exists whereby states guarantee principal and interest through the life of the municipal bonds issued by qualifying municipalities. States may also provide matching funds for certain types of water and sewer projects to their local units of government, particularly for planning purposes. A relatively new factor in the bond market is municipal bond insurance, which has some limited success in lowering borrowing costs for certain municipalities. (Baker-FRC)

WATER RESOURCES OF THE WALKER RIVER INDIAN RESERVATION, WEST-CENTRAL NEVADA,

Geological Survey, Carson City, NV. Water Resources Div.
D. H. Schaefer.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $8.25 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 80-427, December 1980. 61 p, 18 Fig, 14 Tab, 25 Ref.

Descriptors: *Water resources development, *Available water, Groundwater, *Water use, Streamflow, Irrigation water, Wells, Groundwater recharge, Groundwater movement, Water level, Mathematical models, Potential water supply, Evaluation, Hydrologic data, *Nevada, *Walker River Indian Reservation, Surface water.

Increasing interest in expanding the livestock and agricultural operations on the Walker River Indian Reservation, Nev., has prompted the Walker River Paiute Tribe to have the present and available water resources of the reservation appraised and proposed sites for new wells evaluated. Flow of the Walker River into the reservation averages about 113,000 acre-feet a year. Of this amount, about 42,000 acre-feet is used on the reservation, recharging the gound-water system and supplying irrigation water for alfalfa and pasture crops. The water quality of the river water is well suited for these purposes, and the possibility of expanding surface-water use exists. A mathematical model of the ground-water system was constructed to test various assumptions about recharge and discharge rates. The model generated water-level contours that agreed reasonably well with measured water levels, median deviation was 12 feet. With additional data, the model could be used in the future to test the feasibility of evapotranspiration salvage at the seven proposed sites for new stock and irrigation wells. The primary users of ground water on the reservation are phreatophytes and playa surfaces. They allow ground water to be lost to evaporation. About 19,000 acre-feet per year is lost through this mechanism. Domestic and livestock uses account for only about 250 acre-feet per year. Total recharge to the ground-water system amounts to about 30,000 acre-feet per year, and the possibility of more extensive use of ground water on the reservation exists. Quality of the ground water in most areas is suitable for all intended purposes. (USGS)

Descriptors: *Research priorities, *Water resources institutes, *Literature review, *Research needs, *Water conservation, *Water quality control, Organizations, Water quality management, Reviews, Water quality, Water supply, Research facilities, Land use, Runoff, Water use, Water pollution, Water analysis, Technology, Water law, *Office of Water Research and Technology.

Five years (1976-81) of Water Research in Action bulletins are provided, covering Volumes 1-5. Each issue of the bulletin focuses on new knowledge and technology developed through the cooperative research program between the 54 state water resources research institutes and the Office of Water Research and Technology (OWRT), U.S. Department of the Interior. The bulletin is regularly distributed to over 22,000 individuals in all 50 states and a number of foreign countries. The early bulletin issues report on individual research projects from the institutes; the later issues present comprehensive overviews of specific water resources problems, and feature OWRT-funded institute-directed projects that have contributed to the solution of these problems. The numerous topic areas included address land use, flooding, runoff, wastewater, planning optimization, nonpoint source pollution, modeling, erosion, groundwater, water quality, irrigation, reservoirs, waste heat disposal, water sterilization, eutrophication, water conservation and reuse, water law, droughts, acid precipitation, economics, and management. ENERGY SITING IN UTAH: A PROGRAMMING MODEL,
Utah Water Research Lab., Logan.
D. L. Snyder, J. E. Keith, T. F. Glover, and G. L. Wooldridge.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224726, Price codes: A04 in paper copy, A01 in microfiche. Water Resources Planning Series UWRL/P-81/04, June 1981. 55 p, 6 Fig, 32 Tab, 78 Ref. 3 Append. OWRT A-047-UTAH(1), 14-34-0001-9047.

Descriptors: *Energy sources, *Regional development, *Model studies, *Linear programming, *Utah, Systems analysis, Mathematical models, Industrial development, Industrial plants, Electric power industry, Resources development, Industrial production, Resource allocation, Water allocation, Political constraints, Air pollution, Regulations, Legal aspects, Economic impact, Economic evaluation, Economic feasibility, Energy, Agriculture, Air pollution effects.

A study was conducted to examine the economically efficient allocation of resources between existing and proposed production entities, given resource and environmental constraints. The necessary conditions for an optimal input and output allocation were determined for a region constrained by resource availabilities and/or policy constraints, using a conceptual model of a multiple-product firm. A linear programming model was developed to determine optimal water allocation between agricultural and coal-fired power plants and the trade-offs which could occur if electrical generation were increased. Other potential trade-offs examined included coal source restrictions and air quality regulations. Also included were coal mining, transportation costs, and pollutant (S02, nitrogen oxides, particulates) emission rates on a coal and plant basis. Few trade-offs between power generation and agricultural irrigation were noted. However, substantial energy sector changes were discovered as coal capacities were decreased and air quality standards increased, causing a sharp decline in net revenues. Substantial changes in regional economic activity occurred due to these restrictions on development. (Zielinski-MAXIMA)

FIVE-YEAR PLAN FOR WATER RESEARCH OF THE OKLAHOMA WATER RESOURCES RESEARCH INSTITUTE.
Oklahoma Water Resources Research Inst., Stillwater.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224767, Price codes: A03 in paper copy, A01 in microfiche. Oklahoma Five-Year Water Resources Research Plan, submitted to the Office of Water Research and Technology, December 1980. 39 p, 6 Fig, 10 Ref.

Descriptors: *Oklahoma, *Research priorities, *Planning, *Water management, *Water resources development, Rainfall distribution, Land rights, Water supply, Available water, Water shortage, Reservoir construction, Flooding, Groundwater depletion, Streamflow depletion, Municipal water, Industrial wastes, Water pollution, Mineralization, Acid mine drainage, Pollutants, *Five-year plan.

This report outlines the water resource quantity and quality problems of Oklahoma and identifies areas for research emphasis. While water quality problems warrent concern and action, water quantity in certain areas is an overriding current concern. Annual precipitation varies from 56 inches in the humid southeast to 15 inches in the semiarid Panhandle. Furthermore, evapotranspiration and percolation consume about 80% of the annual rainfall, leaving only about 20% available for use. Another major problem has been the lack of a water resources plan. Such a plan, addressing water needs through the year 2040, has now been developed and is under review. A third problem area is an on-going mineral rights dispute with the Osage Indians, causing interruption of construction on four reservoirs. Other identified water quantity problems include flooding, groundwater depletion, low streamwater, inadequate municipal water systems, and urban growth demands. Eleven water quality problems (such as heavy water chloride content, excessive mineralization in groundwater supplies, low stream flows, industrial waste effluents, acid mine drainage) have also been identified. Eight specific research areas have been determined to address the identified priority Oklahoma water resources problems. (Zielinski-MAXIMA)

WATER QUALITY PLANNING IN THE NORTHEAST AND MIDWEST: THE SECTION 208 EXPERIENCE,
Atlantic Environmental Associates, Inc., Waltham, MA.
J. J. Goldrosen, and G. C. McMahon.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224908, Price codes: A10 in paper copy, A01 in microfiche. Report, September 1981. 219 p, 57 Ref, 2 Append. OWRT C-90244-U(No 0525)(1), 14-34-0001-0525(1).

Descriptors: *Water quality, *Research priorities, *Planning, *Institutional constraints, *Political constraints, *Assessments, Economic aspects, Economic feasibility, Economic impact, Cost allocation, Water law, Legal aspects, State jurisdiction, Political aspects, Federal jurisdiction, Policy making, Administrative decisions.

Examination is made of institutional obstacles to water quality planning for urbanizing areas, based on the experiences of Section 208 planning programs conducted in fifteen States of the Northeast and Midwest U.S. The focus is on the institutional, rather than the technical, obstacles to plan implementation. These obstacles include inadequate recognition of water quality problems, difficulty in financing identified solutions, insufficient legal or regulatory authority, local resistance to water quality planning, lack of cooperation among local political units, and lack of cooperation among different government levels. Most of the information used was obtained through direct contact with individuals involved in preparing the Section 208 plans, with nine of the programs selected for on-site visits. An analysis was made of the factors which affected the ability of various agencies to overcome the identified obstacles and to implement solutions to water quality problems. The fifteen States studied were Connecticut, Delaware, Illinois, Indiana, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Ohio, Pennsylvania, Rhode Island, Vermont, and Wisconsin. The Section 208 agencies have fulfilled, to

some extent, all three of their requisite roles, as catalysts, planning consultants, and providers of technical assistance for areawide water quality management. (Zielinski-MAXIMA)

AN ANALYSIS OF THE APPROPRIATENESS OF WIND AND OTHER ENERGY SYSTEMS FOR IRRIGATION WATER PUMPING IN INDIA,
National Aeronautical Lab., Bangalore (India).
S. K. Tewari.
Agricultural Water Management, Vol 4, No 4, p 445-455, December, 1981. 2 Fig, 4 Tab, 14 Ref.

Descriptors: *Wind, *Irrigation, Pumps, Alternative planning, *Energy sources, *India, Water delivery.

Wind energy can be used in a variety of agricultural and industrial applications requiring shaft power, such as water pumping. The appropriateness of wind energy as a source of power for irrigation water pumping was investigated in India in terms of energy availability, cost factors, social priority for the use of particular energy resources for specified applications, organizational and maintenance problems, likelihood of social acceptance, creation of local employment opportunities, and the use of locally available resources. Analysis was carried out on these seven factors in two ways: quantification in respect to possible alternative choices of energy conversion systems, and via the relative importance of these factors, so that a single total value of appropriateness can be computed. Of the options considered, windmills scored the highest appropriateness, with the solar pump being the second best option, followed by photovoltaic conversion. When the qualitative attributes were considered as well, windmills were rated highest, followed by solar pumps, photovoltaic conversion, biogas, solar thermal devices, electrical pumps and diesel pumps. The total appropriateness score including cost factors ranked electrical pumps first, followed by diesel pumps, biogas engines, windmills, solar thermal devices, solar pumps, and photovoltaic devices. CAN THE GOALS OF THE UN DECADE ON WATER SUPPLY AND SANITATION BE ACHIEVED,
Amsterdam Water Works (Netherlands).
C. van der Veen.
Aqua, No 1, p 18-21, 1982. 1 Tab.

Descriptors: *Developing countries, *Water resources development, *Drinking water, Sanitation, Planning, Water supply, *United Nations, *International Drinking Water Supply and Sanitation Decade, Energy, Rural areas, Population dynamics, Political aspects, Economic aspects, Political constraints, *Evaluation.

It is unlikely that the goals of the United Nations International Drinking Water Supply and Sanitation Decade will be met by 1990. Particular problems are population growth, economic recession, large sums spent for armaments, and the increasing cost of energy. However, it is probable that substantial progress will be evident by the end of the decade and that the water goals can be met within two decades. Necessary conditions are: public awareness of needs, development of political priorities, government organization at all levels, adequate planning, community participation, private enterprise involvement, a high status image of water projects and persons working on the projects, good quality management, sound financial basis, and aid to rural areas. THE SHUBENACADIE-STEWIACKE RIVER BASIN STUDY,
Department of the Environment, Halifax (Nova Scotia).
R. H. Bailey.
Canadian Water Resources Journal, Vol 6, No 4, p 187-204, 1981.

Descriptors: *Water management, *River basins, *Water quality management, Bank erosion, Water quality, *Shubenacadie-Stewiacke River, *Nova Scotia, Land use, Economic aspects, Institutional constraints, Regulations, Planning, Water policy, Public participation, Canada.

A study of the 1976-80 Shubenacadie-Stewiacke River Basin, the largest in Nova Scotia, revealed that most of the critical problems in the basin are in an embryonic stage. Water quality problems at present are related to streambank erosion and natural concentrations of undesirable ions in well waters. The major threat to water quality will probably arise from the cumulative effects of small resource use decisions, rather than from the large developments which require intensive environmental scrutiny. The study board concluded that the existing water management framework is not adequate to manage these cumulative developments. Recommendations included: a shift in emphasis from a reactive approach toward a planning approach, an increase in capability to handle long-term cumulative effects of economic activities, coordination among agencies at all levels of government, and an increase in public participation in development and implementation of these objectives. Instituting a Water Resources Management Center at a Nova Scotia university was also suggested. (Cassar-FRC)

FIVE-YEAR PLAN OF THE WATER RESOURCES RESEARCH CENTER,
College of the Virgin Islands, St. Thomas.
R. U. Champney.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-231960, Price codes: A02 in paper copy, A01 in microfiche. Report, July, 1981. 8 p, 1 Tab.

Descriptors: *Virgin Islands, *Research priorities, *Planning, *Water management (Applied), *Water resource development, *Water shortage, Water supply, Water demand, Water use, Groundwater potential, Potable water, Desalination, Semiarid lands, Water importing, Brackish water, Wastewater treatment, Water quality.

Water research and development needs for the Virgin Islands for the five years starting with fiscal year 1982 are summarized. Water problems relate to the observation that water supply falls far short of water demand, and that the available water is largely of subpotable quality. This plan focuses on evaluating individual Virgin Island watersheds relative to water storage capacity, recharge rates, on permissable water withdrawal rates on one hand, and on investigating possible methods of achieving and maintaining high quality water in the public water distribution system, on the other. Average annual rainfall varies from 40-45 inches, but demand for rainfall by evapotranspiration exceeds the supply, and the Islands are classified as semi-arid. For all practical purposes, the Islands have no surface water, and groundwater resources are largely unknown and brackish. Water deficits have been addressed by water importation and desalination plant installation; the former is inefficient. Major problems include: inadequate potable water supply and public distribution system; polluted water in the distribution system; and inadequate wastewater treatment facilities. The highest research priority is a needed assessment of groundwater resources. The second highest priority will be studies of pollution in public water related to source identification and remedy. (Zielinski-MAXIMA)
W82-05526

A FIVE-YEAR PLAN OF WATER RESOURCES RESEARCH.
Auburn Univ. AL. Water Resources Research Inst.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-232042, Price codes: A03 in paper copy, A01 in microfiche. Report, 1981. 39 p, 2 Fig, 3 Tab, 33 Ref.

Descriptors: *Alabama, *Research priorities, *Planning, *Water management (Applied), *Water resources development, Water supply, Water resources institutes, Water demand, Groundwater availability, Irrigation water, Aricultural runoff, Groundwater pollution, Coal mining, Strip mine wastes, Surface water availability, Sediment load, Water quality, Water use, Legal aspects, Institutional constraints.

This plan includes a brief description of Alabama's water resources, physical geography, and geology. The use of Alabama's water resources, estimated at 52 billion gallons/day, is described, and water resources problems are identified. Data indicate that there is no general water shortage at the present time and that none is anticipated. Projections of water use are included to the year 2020. Six problem areas to be addressed were identified from a listing of 27 major water and related land resources problems facing Alabama. The six problems for research plan focus are: inadequate data and methods concerning water supply as related to groundwater quantity and quality; a projected competing increased demand on groundwater resources in southern Alabama for irrigation; groundwater contamination from agricultural and other practices/sources, including the need for improved monitoring; adverse effects of strip and subsurface mining on water supplies; and heavy sediment loads degrading water quality. The six problem areas fall under one or more of five generic research categories (e.g., atmospheric/hydrologic/hydraulic processes; water quality processes; water resources management; ecologic-environmental relationships; institutional, legal, and other constraints. (Zielinski-MAXIMA)
W82-05527

FIVE-YEAR WATER RESOURCES RESEARCH AND DEVELOPMENT GOALS AND OBJECTIVES FOR WYOMING.
Wyoming Univ., Laramie. Water Resources Research Inst.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-231978, Price codes: A06 in paper copy, A01 in microfiche. Report, July, 1981. 96 p, 2 Fig, 12 Tab, 7 Ref, 1 Append.

Descriptors: *Wyoming, *Research priorities, *Planning, *Water management(Applied), *Water resources development, Water supply, Water quality, Water use, Water conservation, Flurial sediments, Flooding, Water harvesting, Weather modification, Groundwater recharge, Water rights, Legal aspects, Institutional constraints, Economic aspects.

This report dicusses Wyoming's land/and water resources, water uses and problems, water and related land planning and development activities, and priority water issues that need attention. Wyoming contains seven river basins and the headwaters of four major river basins, with over 90% of the water flowing through Wyoming originating within its boundaries. Large groundwater stores are also present. Wyoming water use is constrained, however, by the appreciation system of water laws and by compacts with neighboring states. Further, water competition among Wyoming's three most prosperous economic sectors (minerals, recreation/tourism, and agriculture) will become increasingly serious as natural resources development continues. Issues needing attention in the water quantity area are: water availability, flurial morphology, flooding, water harvesting, weather modification, and groundwater recharge. Water quality issues are related to municipal, agricultural, and industrial concerns. Water use and conservation topics include: water use efficiency in food/fiber production and for municipal/industrial use, institutional incentives for conservation, coservation practice impacts on hydrologic systems, water reuse, and instream flow needs. Economic/institutional water concerns are also discussed. (Zielinski-MAXIMA)
W82-05528

VIRGINIA WATER RESOURCES RESEARCH CENTER FIVE-YEAR PLAN.
Virginia Polytechnic Inst. and State Univ., Blacksburg. Virginia Water Resources Research Center.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-231986, Price codes: A08 in paper copy, A01 in microfiche. Report, June, 1981. 143 p, 3 Fig, 7 Tab, 1 Append.

Descriptors: *Virginia, *Research priorities, *Planning, *Water management(Applied), *Water resources development, Management planning, Information systems, Land management, Surface water availability, Groundwater pollution, Environmental protection, Water quality, Monitoring, Sludge disposal, Groundwater management, Water supply, Water use.

This report describes Virginia's water resources, the significant problems affecting them, and a five-year plan for dealing with these problems from fiscal year 1983-87. Priority problems were identified in each of eight areas: water supply, inventory and monitoring, resource management, nonpoint source pollution, flood damage abatement, outdoor recreation, waste treatment, and marine environment, with the first four identified as the highest priority problem areas. The most significant water resources problem can generally be characterized as problems of management, with the most pressing being the lack of a comprehensive water resources management plan. The five-year activity plan is based on attainment of eight specified goals, each having specific objectives. Two goals concern public education and information dissemination activities to increase public awareness of water resources. A third goal involves continued identification of current priority water problems and current information on critical problems. The remaining five goals address the solution of specific priority problems: developing a comprehensive resources management plan; land management plans for surface and groundwater protection; a sludge-disposal polity; improved routine water quality monitoring; and methods to promote an outdoor ethic. Delineation of 60 important water problems facing Virginia is included. (Zielinski-MAXIMA)
W82-05529

MICHIGAN FIVE-YEAR WATER RESOURCES RESEARCH AND DEVELOPMENT PLAN: FISCAL YEARS 1982-1986.
Michigan State Univ., East Lansing. Inst. of Water Research.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-231994, Price codes: A04 in paper copy, A01 in microfiche. Report, 1980. 47 p, 5 Tab, 15 Ref.

Descriptors: *Michigan, *Research priorities, *Planning, *Water management(Applied), *Water resources development, Hazardous materials, Toxins, Water pollution, Nonpoint pollution sources, Pollution load, Eutrophic lakes, Wetlands, Groundwater pollution, Economic aspects, Water quality, Water use, Water supply.

As a background and basis for Michigan's five-year water resources research plan, this report provides a general overview of the status and problems of Michigan's water resources. While Michigan has an abundant and diverse source of freshwater due to its geographical location within the upper Great Lakes region, nearly all of its urban/industrial/agricultural wastes drain to the Great Lakes where their impact is accentuated due to the slow flushing rate of the Great Lakes system. Michigan's most critical water resource problem is, hence, water quality management. The continued availability of suitable water to meet diverse State and regional needs is dependent on actions to prevent water quality degradation. To assist the resolution of Michigan's water resources problems, this research plan is focused on three major areas: development of a comprehensive State water resources atlas; continuing and expanding technology transfer and information dissemination; and conducting a research program under six priority categories. These categories concern; fate/transport/effects of toxic/hazardous water pollutants; mechanisms influencing nonpoint source pollution; control and management strategies to minimize entrophication impacts on lakes; defining functinal and economic value of wetlands and effects of physical/chemical/biological variables on groundwater quality and quantity. (Zielinski-MAXIMA)
W82-05530

A FIVE-YEAR PLAN FOR WATER RESEARCH IN COLORADO,
Colorado Water Resources Research Inst., Fort Collins.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-232059, Price codes: A07 in paper copy, A01 in microfiche. Report, January, 1981. 127 p, 20 Fig, 8 Tab, 15 Ref, 3 Append.

Descriptors: *Colorado, *Research priorities, *Planning, *Water management(Applied), *Water resources development, Water quality control, Water supply, Water use, Water demand, Competing use, Runoff forecasting, Groundwater recharge, Heavy metals, Water pollution, Groundwater pollution, Saline water, Mineral industry.

This report covers a detailed description of Colorado water resources, the institutional interrelationships of Colorado water organizations, and the projected five-year water resources research plan. A listing of 22, 14, 21, 36 and 31 researchable water problems of high water priority for Colorado is given for the five generic research categories: atmospheric/hydrologic/hydraulic processes; ecological-environmental relationships; water quality processes/prediction/protection; water resources management; and institutional/political/legal/behavioral/economic analysis, respectively. These priority water problems reflect four primary objectives: maximize the beneficial use of the annual water supply; augment the annual supply; minimize water quality degradation; and resolve competitive demands for water. The five-year research program will be drawn from 49 research problem areas under these four primary objectives. The research needed for each of this area is tabulated. A programming guideline protocol for problem-solving water research using a programming and execution process which includes program evaluation is provided. An inventory of current water resources studies in Colorado is also included. (Zielinski-MAXIMA)
W82-05531

FIVE YEAR WATER RESOURCES RESEARCH PLAN FOR THE STATE OF CALIFORNIA,
California Univ., Davis. Water Resources Center.
R. W. Hinks, and J. H. Snyder.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-232034, Price codes: A05 in paper copy, A01 in microfiche. Report No 49, October, 1980. 73 p, 7 Fig, 9 Tab, 34 Ref. 14-34-0001-0480, UCLA-WRC-W-100.

Descriptors: *California, *Research priorities, *Planning, *Water management(Applied), *Water resources development, *Groundwater management, Competing use, Water use, Water demand, Water supply, Available water, Groundwater reservoirs, Wastewater renovation, Water conservation, Water quality, Environmental production, Institutional constraints.

This report presents an analysis of the current status of California's water resources problems and identifies areas of recorded research for a five-year planning period of fiscal year 1983-87. Priority classification tables are presented which indicate the relative importance of specific areas of research activity. A major characteristic issue of California water resources between now and the year 2000 is the inevitable competition between agricultural and nonagricultural uses for a strictly limited and fixed water supply. Background information is given on physical factors that influence California water resources, and the use of these resources is delineated with respect to water demand, development, management alternatives, and identified problem areas to meet the expected future demand. Problems included additional construction needs, and current management policy regarding groundwater, wastewater reclamation/conservation, environmental protection, and water quality. Research needs are proposed under six areas. Thirty-two research needs are prioritized under categories of very high, high, and medium priority. Very high priority research needs (of 9 identified), include: water quality related to health and salinity; water development and management alternatives; and improved information dissemination for all aspects of water research activities. (Zielinski-MAXIMA)
W82-05532

NEVADA WATER RESOURCES RESEARCH 1982-1987,
Nevada Univ. System, Reno. Water Resources Center.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236928, Price codes: A09 in paper copy, A01 in microfiche. Report, October, 1980. 80 p, 6 Fig, 20 Tab, 3 Append.

Descriptors: *Nevada, *Research priorities, *Planning, *Water management(Applied), *Water resources development, Groundwater recharge, Aeration zone, Flow characteristics, Groundwater availability, Water supply, Water use, Deep wells, Conjunctive use, Coal mining, Water quality, Water conservation, Water reuse, Institutional constraints, Legal aspects.

Water resources problems and research needs for Nevada are described. Water resources are detailed under categories of surface water, groundwater, and the available water supply. Uses of water resources (e.g., irrigation, livestock, mineral industry, electric power, municipal and industrial) and conflicts in water uses are discussed. The most urgent problem areas needing attention are: groundwater recharge, unsaturated zone flow mechanics, groundwater availability, deep aquifer studies, conjunctive use, water reuse, water conservation, legal/institutional issues, and effects of mining on water quality. These problem areas are described in matrix form relative to specific hydrographic regions. Identified research priorities are arranged under five broad categories: atmospheric/hydrologic/hydraylic processes (e.g., flow mechanics in the unsaturated zone, groundwater and aquifer recharging, modeling rainfall-runoff-recharge in arid regions); ecologic-environmental relationships (methodology to slow/reverse nutrient overloading, quantitative evaluation of algal growth processes); water quality (soil-water interactions regarding contaminants, groundwater contamination, pollutant transport); resources management (long-term effects of energy/mineral development, agricultural water conservation, water resources planning, water reuse innovations); and institutional/political/legal/behavioral/economic analysis. (Zielinski-MAXIMA)
W82-05533

INTERNAL RATES OF RETURN DERIVED FROM THE PAY-BACK PERIOD,
Hershev - The Inter-Kibbutz Economic Unit, Tel Aviv (Israel).
Y. Goldschmidt, and L. Shashua.
Omega - The International Journal of Management Science, Vol 8, No 6, 1980. p 695-696. 2 Tab. OWRT B-080-ARIZ(6).

Descriptors: *Rate of return, *Financial feasibility, *Economic yield, *Cost analysis, *Algorithms, Mathematical studies, Economic aspects, Economics of scale, Economic efficiency, Economic evaluation, Economic justification, Cost allocation, Econometrics, Financing, Input-output analysis, Investment, Payment, Management planning.

Simple tools (tables and rules of thumb) are developed for deriving the internal rate of return (IRR) from the pay-back perion (PBP), to bridge the gap over the disparity between theory and business practice regarding capital budgeting. The PBP of a proposal for an investment project is the time needed for accumulated expected cash flow (net returns) to reach the initial cost of the investment; the IRR of the project is the rate of discount which equates the present value of the expected cash flow to the initial cost of the investment.

Library U. of I. Urbana Champaign

Given the PBP and the expected service life, the IRR is derived directly from tables, or roughly approximated by simple rules of thumb. Initially, the PBP can be used to provide a rough screen of proposed investment projects; final screening is carried out by checking the IRR, using the tables. The table provide percentage values of service life (from 5-14 years) of the IRR and of the certainty equivalent rate of return, as a function of the number of years (2.0-7.0) of pay-back. If a proposed investment project is expected to yield a constant cash flow, uncertainty can be assumed by approaching the cash flow as if it would decline with time. Hence, using the appropriate table (or rule) provides both the expected and the certainty equivalent IRR of the investment. These tools enable decision-makers to introduce an uncertainty effect into the straight-forward PBP computation, which permits a check of the sensitivity of a proposed investment. (Zielinski-MAXIMA)
W82-05542

DOMESTIC WATER CONSERVATION RESEARCH PLAN,
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236613, Price codes: A02 in paper copy, A01 in microfiche. Report, July 7, 1978. 17 p, 5 Tab. (No 8544)(1).

Descriptors: *Water conservation, *Research priorities, *Metropolitan water management, *Domestic water, *Water costs, Water use, Planning, Policy making, Public policy, Economic evaluation, Management planning, Available water, Water supply, Heated water, Water management, Reclaimed water, Water reuse.

A four-year plan (1978-1982) is described which identifies research needs to improve domestic water conservation. The plan addresses various needed assessments concerning hardware and water management practices for both indoor (e.g., toilet water, bath and shower water, laundry water) and outdoor (landscape maintenance) domestic uses of water. Research needs concerning ten indoor water themes (e.g., water use and energy impacts, economic analysis, institutional incentives, user acceptance) and five outdoor water themes (e.g., baseline data, new device technology, use of reclaimed water) are delineated. Seventeen water resource issues that directly or indirectly relate to residential water conservation are brefly reviewed, with the fastest growing cost issue being energy needed for pumping and heating water. The objectives of this research program are targeted providing basic data needed by policy makers and water managers for implementing water conservation policy; and reducing current residential water usage by 50% by increasing water use efficiency. Assuming an annual domestic water use of 100,000 gallons at a cost of $0.55/1000 gallons, a savings of $2.2 billion dollars is possible in water costs alone; if energy is included, the savings could potentially exceed $8 billion dollars/year. (Zielinski-MAXIMA)
W82-05547

INSTITUTIONAL PROBLEMS OF WATER QUALITY PLANNING IN URBANIZING AREAS IN THE PACIFIC NORTHWEST,
Dornbusch (David M.) and Co., Inc., San Francisco, CA.
K. Wehbring.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236688, Price codes: A05 in paper copy, A01 in microfiche. Report, September, 1980. 75 p, 1 Tab, 29 Ref, 1 append. OWRT C-90094-U(No 9433)(1), 14-34-0001-9433.

Descriptors: *Water quality management, *Planning, *Urbanization, *Institutional constraints, *Regional development, Urban watersheds, Water quality, Water quality control, Urban drainage, Urban areas, Urban hydrology, Urban planning, Legal aspects, Economic aspects, Government finance, Political aspects, Community development, Social aspects, Social needs.

Institutional obstacles (including legal, financial, organizational, inter-governmental, political, and social aspects) revealed in the 208 program water quality planning process of 12 Pacific Northwest urbanizing areas are analyzed to assess their impact on planning. Attention is focused on the identification and analysis of institutional obstacles related to wastewater management, urban stormwater runoff, and agricultural runoff. The 208 plans for the 12 areas studied are identified by the major regional city in the planning area; these cover three cities in Washington (Seattle, Everett, and Vancouver), five in Oregon (Portland, Salem, Eugene, and Medford/Ashland), three in Idaho (Boise, coeur d'Alene, and Pocatello), and one in Alaska (Anchorage). Wastewater management obstacles identified are: public opposition to increased water quality costs; land use and urban growth controversies; political aspects of annexation and incorporation; and the existing multilicity of sewerage agencies. Identified obstacles related to urban stromwater and agricultural runoffs are: lack of understanding of water quality problems and lack of will to undertake water quality improvement programs; lack of federal assistance for urban stormwater runoff control; fragmentation of authorities, both jurisdictional and inter-governmental, affecting water quality planning for agricultural and urban runoff; the absence of adequate codes and ordinances for enforcing water quality needs; and the lack of implementing authority by the councils of government which developed the areawide 208 plans. Minnesota Univ., St. Paul. Coll. of Forestry.
K. N. Brooks, H. M. Gregersen, E. R. Berglund, and M. Tayaa.
Water Resources Bulletin, Vol 18, No 2, p 245-250, April, 1982. 1 Fig, 4 Tab, 22 Ref.

Descriptors: *Cost-benefit analysis, *Economic analysis, *Watershed management, Benefits, Rehabilitation, Project planning, Erosion, Sedimentation, Loukkos River, Morocco, Soil management, Land use, Channel improvement, Reforestation, Reservoirs, Irrigation.

A practical, low cost approach for integrating physical and biological considerations for economic analysis of proposed watershed rehabilitation projects is illustrated via a project for the Loukkos Basin in northern Morocco. The economic analysis is conducted in four steps: (1) defining present and proposed physical conditions of erosion, sedimentation, etc., (2) developing value estimates and value flow tables in terms of monetary values, (3) calculating project worth by such measures as net present worth or economic rate of return, and (4) testing the sensitivity of the measures of project worth to change in assumptions. The four steps are applied to an analysis of the 182,000 ha Loukkos watershed, which is physically degraded, with compacted soil surface, nutrient depletion, soil salinizatin, and mass movement problems. Proposed corrective measures include road construction, channel stabilization, reforestation, pasture management, and planting olive trees, at a total cost of $26.1 million. Analysis indicated that the net benefits would be negative for the first 7 years of the project and rise to $21.71 million per year by the fiftieth year. (Cassar-FRC)

LOCAL ATTITUDES TOWARD ALTERNATIVE USES OF A RESERVOIR PROJECT,
Ohio State Univ., Columbus. Dept. of Development Sociology.
T. L. Napier, M. V. Carter, and E. G. Bryant.
Water Resources Bulletin, Vol 18, No 2, p 211-219, April, 1982. 5 Tab, 27 Ref.

Descriptors: *Attitudes, *Reservoirs, *Water resources development, Public opinion, Social impact, Economic impact, Ohio, Alternative planning, Multipurpose reservoirs, Surveys, Benefits, Cost-benefit analysis, Recreation.

Residents of a dispersed rural central Ohio community were asked about their attitudes concerning the funds allotted for a multi-purpose reservoir built in that area about 10 years previously. As a group, the local people were satisfied that the lake project had been built with the available resources in preference to several other development options (industrial parks, better public services, state or national park, public water supply wells, aid to small business, help for the poor, construction of several smaller impoundments, and allocations for private recreational development). Only one option, keeping the land in its original state of forests and agriculture, was slightly favored over the lake project. A vested interest perspective was used to investigate socio-demographic, attitude, and cost assessment factors. The findings showed that costs and benefits were good predictors of attitudes toward the project. That is, persons who benefited from the lake project had favorable attitudes toward the lake, while those who experienced costs as a result of the project favored alternate options. Long-term residents tended to favor the alternative development options, whereas nonfarmers, persons with higher educational achievement and those with negative perceptions of recreationists tended to favor the lake project. Descriptors: *Water resources development, *Research priorities, Water quality, Resources management, Planning.

Water resources research is essential to the protection of water quality and to the wise use of limited water resources. Research management must prioritize study topics and foster their productive completion in order to maximize research productivity. However, the water research management struc-

ture found in the Federal government and in the States is strongly influenced by pervasive trends toward consumerism, which identifies current users and makes them the judges of worth; fiscal constraint, which tends to focus research on user-recognized early payoffs; centralized management; and the use of research for other social objectives. The research prioritization and management structure which these trends have created was examined in the microcosm of its application at the Utah Water Research Laboratory. This review indicated that research productivity is seriously diluted by the failure of research users to communicate their particular needs to researchers and by the effects of consumerism in terms of ephemeral and volatile priorities which work against sustained research thrusts over the durations required to deliver research results to users who recognize their needs. Corrective approaches to research management might include incremental research prioritization and greater use of advisory councils to facilitate user-research interaction. The only firm conclusion drawn is that empirical studies of the performance of alternatives in research management structure are needed. (Carroll-FRC)

TURKS PRESS FORWARD WITH AMBITIOUS DAM PROGRAMME,
G. Tansey.
World Water, Vol 5, No 3, p 22-25, March, 1982. 1 Fig.

Descriptors: *Water resources development, *Financing, *Developing countries, *Turkey, Dam construction, Hydroelectric power, Irrigation, Reservoirs.

Rising oil costs have encouraged water resources development in Turkey, which currently uses only 10% of its 100 TWh potential hydropower. Installed capacity is 1171 MW. Thirteen projects (7219 MW capacity) are underway, and 34 projects (6529 MW) are in the planning stage. The Hasan Ugurlu, a 179 m high earthcore rockfill dam completed in 1979, was the first major dam built by a Turkish company with a Turkish workforce. Only 6 minihydro plants have been built, all in remote areas. No studies have been done on the minihydro potential. The goal for increasing the present 40,000 sq km of irrigated land is 100,000 ha per year. Irrigation projects have been moving rapidly near the Mediterranean and Aegean coasts, but more slowly in the central and east. Financing water projects has been a major deterrent to development. Water prices have been unrealistically low, and foreign money is hard to obtain. This lack of funds has slowed several major dam construction projects. Other difficulties are water rights conflicts with Syria and Iraq and a shortage of skilled workers. (Cassar-FRC)

A REVIEW OF THE BENEFIT-COST ANALYSES OF TWO SOUTHERN ALBERTA DAMS,
Calgary Univ. (Alberta). Dept. of Civil Engineering.
M. Gysi.
Canadian Water Resources Journal, Vol 5, No 1, p 76-86, 1980. 8 Ref.

Descriptors: *Cost-benefit analysis, *Benefits, Water management, *Canada, Dams, Oldman River Dam, Red Deer River Dam, *Alberta, Irrigation, Industrial development, Employment, Economic justification.

Benefit-cost ratios for the Red Deer River and Oldman River dams in southern Alberta were based on grossly inflated benefits. The Phase I Study for Oldman River Dam used a multiplier of 1.5 to compute the secondary benefits from the primary (irrigation) benefits. Using a more acceptable multiplier of 0.1 reduces benefits by $66 million. In addition, the primary and secondary employment wages benefits ($16.5 million) should not have been included, considering Alberta's fully employed economy. These deductions change the original benefit/cost ratio of 1.59 to 0.65. Phase II of the Oldman River Study removed huge farmers' costs of irrigation and added an unwarranted 45% regional secondary benefits. Benefit/cost ratios were subjected to sensitivity analysis fby four methods and the most favorable reported, rather than the more realistic 1.1-1.3. The Red Deer River Dam, a flow regulation dam already approved, listed employment benefits (dam and resulting industrial development) as the only benefits. The major error was the assumption that all industrial development was attributed to the dam. In fact, employment benefits from a petrochemical plant, approved for construction before any commitment to build the dam, were also attributed to the dam. The decision to build Red Deer Dam was political and not based on economic reasons. Alberta Environment has made efforts to improve and standardize benefit/cost methods. (Cassar-FRC)

UNIFIED RIVER BASIN MANAGEMENT,
Waterloo Univ. (Ontario). Dept. of Geography.
B. Mitchell.
Canadian Water Resources Journal, Vol 5, No 2, p 87-95, 1980.

Descriptors: *Water basin development, Water management, *Water policy, Planning, Management planning, Institutional constraints, Symposium.

A symposium on unified river basin management was presented May 4-7, 1980, at Gatlinburg, Tennessee, by the American Water Resources Association and Tennessee Valley Authority with assistance from other organizations. Three keynote addresses concerned the following subjects: the accomplishments and challenges of the TVA, the history and difficulties faced by integrated river basin development, and evolution of organizational arrangements for river basin management. Authors of the 61 papers did not agree on a definition or the universal need for unified river basin management. A variety of approaches have been successful in the past, depending on local physical characteristics, public attitudes, etc., and may not be suitable for the future. Success of a management program depends on whether the managers or the public are evaluating the program. Planners should be in closer contact with the realities of implementation. Trade-offs and compromises are necessary in river basin planning. Constraints should be recognized and incorporated into solutions rather than reaching for a theoretically optimum solution. THE EIGHTIES--IMPLICATIONS FOR WATER MANAGEMENT,
Ministry of State for Economic Development, Ottawa (Ontario).
C. D. Burke.
Canadian Water Resources Journal, Vol 5, No 2, p 1-12, 1980. 46 Ref.

Descriptors: *Planning, *Water management, *Water demand, Canada, Long-term planning, Population dynamics, Employment, Energy, Biological treatment, Water pollution, Water quality, Climatology, River basins, Forecasting, Water conservation, Research priorities.

An address presented at the Keynote Session of the CWRAS National Conference in 1980 looks 10-20 years into the future for three reasons: to eliminate self-solving problems, to pick up growth-related problems, and to stay ahead of needs. Trends in population numbers and distribution, employment, fuels, and energy in Canada are predicted. In environmental issues there will be a shift in emphasis from the visible pollutants to the insidious pollutants (polychlorinated biphenyls, acid rain, etc.) and an emphasis of on global environmental problems such as climate change. Water management issues vital during the next 10 years are described. The river basins subject to most pressure in the next decade are those located in Southern Alberta, the Saskatchewan, the Fraser Estuary, the Mackenzie, and the Great Lakes. Municipal water demands will show less growth except in Calgary and Edmonton. Hydropower will concentrate on low-head dams, in-stream sites, and tidal power. Heavy water demands for energy development can be expected in Alberta. More attention will be given to water use efficiency, climate variability, biological sewage and water treatment, trace levels of pollutants in water, and the danger of a burgeoning government water management bureaucracy. (Cassar-FRC)

WATER MANAGEMENT IN THE METROPOLITAN TORONTO REGION,
Metropolitan Toronto and Region Conservation Authority, Downsview (Ontario). Water Resource Division.
M. R. Garrett.
Canadian Water Resources Journal, Vol 5, No 1, p 78-86, 1980. 2 Fig.

Descriptors: *Storm water, *Urban runoff, *Water management, *Metropolitan water management, Runoff, Land development, Land use, Land acquisition, Flood plains, Risks, *Toronto, Ontario, Planning, Watershed management, Urban hydrology, Urban drainage, Storm runoff, Flood control, Flood plain management, Flood protection, Urban planning, Urban watersheds.

The Metropolitan Toronto and Region Conservation Authority began its comprehensive watershed plan with a 3 year data gathering process. Some preliminary conclusions were developed. The hazard land acquisition program should be continued and vulnerable structures removed. An erosion control works program should be continued. Remedial works should be continued. Remedial works should be continued so that no development is exposed to the risk of a 100-year flood, or greater in some cases. Major flood damage areas can be redeveloped if the risk level has been reduced to a satisfactory level. Risk must be defined as risk to life and property, not minor inconvenience. The flood control program must recognize the varying valley characteristics. Objectives have been established for storm water management in the areas of provision of servicing, reduction of hazard, conservation, planning, and economics. (Cassar-FRC)

WATER MANAGEMENT IN THE MARITIMES,
New Brunswick Dept. of Fisheries and Environment, Fredericton.
W. F. G. Cardy.
Canadian Water Resources Journal, Vol 5, No 3, p 26-33, 1980.

Descriptors: *Water management, *Attitudes, *Water policy, Canada, Nova Scotia, New Brunswick, Prince Edward Island, Water supply, Water use, Public opinion, Water resources development, Planning, Hydroelectric plants, Multipurpose projects.

The abundant water resources of Canada's Maritime provinces, New Brunswick, Nova Scotia, and Prince Edward Island, have been more than sufficient to satisfy the demands of the 1.65 million population. Until recently, water problems such as pollution control, control of water course alterations, and water rights establishment have been handled on an individual basis. The present job of water managers is to shape public attitudes toward water resources. The concepts that must be communicated are that minor crises are usually part of a larger, developing problem and that water is a valuable resource. With a reshaping of attitudes toward water, management policies can be implemented with respect to multiple use of hydrostation reservoirs, protection of drinking water sources, and improved reservoir operation. STORMWATER MANAGEMENT - ONE DEVELOPER'S EXPERIENCE,
Major Holdings Ltd., Kitchener (Ontario).
G. W. Wright.
Canadian Water Resources Journal, Vol 5, No 2, p 68-77, 1980. 3 Fig.

Descriptors: *Political constraints, *Storm water, *Urban drainage, Planning, Drainage engineering, Ontario, Urban development, Water policy, Water management.

Major Holdings Limited, and Ontario developer, planned advanced stormwater management for some large resiintial developments but experienced political problems and resistance to innovative methods. Much enthusiasm for the plans was evident among designers and consultants. However, when the bureaucracy realized that policy changes were necessary, resistance developed. Responsibility for decisions on storm water management was passed from agency to agency. As a result, management designs have been abandoned for current practices, which are more expensive and produce less environmental benefits. (Cassar-FRC)

CONFLICT OVER WATER SOURCES PREDICTED BY GLOBAL STUDY.
World Water, Vol 5, No 4, p 49, 51, April, 1982. 3 Tab.

Descriptors: *Water supply, *Population dynamics, *Irrigation, Prediction, Water resources development, Environmental effects, Forests, Agriculture, Water pollution, Energy, River basins, Developing countries, Wastewater treatment.

The 766-page book, 'The Global 2000 Report to the President', commissioned in 1977 by former President Carter, predicts the status of world population, environmental conditions, and natural resources for the year 2000. The predictions have serious implications for water resource planners. The population increase to 5900-6800 million will be concentrated in already overpopulated and underdeveloped nations and in urban areas. Conflicts over water resources will intensify, especially in multinational basins. Disparities between rich and poor nations will increase. total irrigated land may rise from 223 million ha in 1975 to 273 million ha by 1990. Costs of improving ineffective irrigation and drainage systems are $36,000 million (1975 prices). Increasing irrigation will add to salinity problems downstream from projects. Deforestation, which profoundly affects water resources, will continue until about 2020, when the total forest area will stabilize at 18 million sq km. The environmental will suffer loss and deterioration of agricultural soil caused by soil erosion, stabilization, pollution, and water shortages. Burning of farm wastes for fuel reduce the nutrients and reduce the soil's ability to retain nutrients and water. Water withdrawals in 2000 will be 1800-2300 million cu m, 5 times the present level. The huge sums of money required for treatment of water pollution and wastewater may not be available in developing countries. (Cassar-FRC)

6C. Cost Allocation, Cost Sharing, Pricing/Repayment

A SPATIAL COSTING SYSTEM FOR DRINKING WATER,
Municipal Environmental Research Lab., Cincinnati, OH. Drinking Water Research Div.
R. M. Clark, V. F. Fender, and J. I. Gillean.
Journal of the American Water Works Association, Vol 74, No 1, p 18-26, January, 1982. 11 Fig, 2 Tab, 7 Ref.

Descriptors: *Cost allocation, *Water treatment, *Water distribution, Metropolitan water management, Accounting, Costs, Data processing, *Kenton County, *Kentucky, Depreciation, Management planning.

A survey of the data collection and analysis procedures in large water utilities conducted throughout the United States beginning in 1974 revealed that the procedres varied widely and were generally inadequate for cost assessments. A technique has been developed for data collection and analysis to fulfill both managerial and accounting needs. This technique, based on a matrix, spatial assignment concept, was tested with a water supply simulation model and then implemented in Kenton County, Kentucky. The calculation of unit costs is based on revenue-producing water (RPW) rather than total water treated. Each month, the RPW by cost zone is entered onto a worksheet. costs are first charged to cost centers within the physical system and then transferred in increments from the cost centers to the appropriate cost zone, based on the flow of RPW within the zone. The system is designed to produce supplemental management reports and a cost analysis report. Examination of the report unit costs by zone will show trends or deviations from normal costs within a distribution area. A depreciation base was established for water district assets so that depreciation could be properly treated as an operating cost. The system supplied useful management reports and provided the basis for a proposed rate increase. (Carroll-FRC)

THE REAL PRICE OF URBAN WATER,
West Virginia Univ., Morgantown. Regional Research Inst.
P. C. Mann, and P. R. LeFrancois.
Journal of the American Water Works Association, Vol 74, No 1, p 22, January, 1982.

Descriptors: *Pricing, *Municipal Water, *Economic aspects, Water shortage, Water conservation, Public opinion, Industrial water, Maintenance, Water distribution, Inflation, History, *Water supply.

Public perception of the relative importance of water pricing appears to moving away from the neglect which it previously suffered. Recent water shortages have produced much activity among states and user groups to assure future supplies. Inflation and increased quality demands have resulted in more frequent rate increases in the recent past. Growing consumer militancy has generated sentiment to sheild low-income consumers of water service from higher rates, particularly in rural areas. Urban water underpricing has induced water utilities to defer both system maintenance and capital replacement. although the nominal price of water has been increased in most areas, the real price has, on the average declined in the past decade because of inflation. Only the real price of industrial water, not residential or commerical water, increased during 1970-81. If this underpricing is continued, urban water consumers may be confronted at some point with the prospect of either massive increases in rates to cover the renovation of the entire system, or substandard and unreliable water service. (Carroll-FRC)

ESTIMATION OF SUBSTITUTION POSSIBILITIES BETWEEN WATER AND OTHER PRODUCTION INPUTS,
EG and G Environmental Consultants, Waltham, MA.
F. G. Babin, C. E. Willis, and P. G. Allen.
American Journal of Agricultural Economics, Vol 64, No 1, p 148-151, February, 1982, 2 Tab, 16 Ref.

Descriptors: *Water demand, *Pricing, Water use, Industrial water, Economic aspects, *Water rates.

This study examines water use at the standard industrial classification two-digit industry level and employs improved water price information. The translog form used offers advantages in that the ability to model production relationships with several inputs exists without imposing stringent conditions on the elasticity of substitution. From data for the individual sector estimates, it was concluded that changes in the price of water will have little effect on water usage. However, a 1% rise in the price of water would result in a 0.16% drop in the use of capital for the paper and pulp industry. Such a small response makes sense due to the relatively small cost share of the water input. On the other hand, a 1% rise in the cost of capital services for the same industry would lead to a 0.71% reduction in water use. It cannot be assumed that the industries studied in this paper can be pooled on the basis of identical parameters. Estimates found capital and production labor to be substitutes in all industry groups analyzed. However, all other pairs of inputs ere found to be substitutes for some industries and complements for others. Water planners are thus likely to find that elasticities based on pooled data are unreliable indicators of price responsiveness for their specific industrial customers. (Baker-FRC)

RESTRUCTURATION OF THE WATER TARIFF SYSTEM FOR IRRIGATION DISTRICTS IN MEXICO.
Secretaria de Agricultura y Recurosos Hidraulicos, Mexico City.
A. Olaiz.
Journal of Hydrology, Vol 51, No 1-4, p 29-40, May, 1981. 2 Fig, 2 Tab, 8 Ref.

Descriptors: *Irrigation programs, *Design criteria, Planning, Model studies, Water use, *Mexico, Tariff, *Economic aspects, Cost sharing.

In the Federal Water Law of 1972, the Mexican government declared irrigation districts to be for the public benefit and established the obligation of all users to contribute to their self-sufficiently by covering the cost of the services they receive on an equitable basis as set by the law. In order to meet expected growth in population and water demand between the years 1975 and 2000, the total irrigated area must be doubled; the efficiency of water use in irrigated plots must be increased by 15% and efficiency increased 8% in total distribution systems. Three major goals were set for 1982: to reach financial self-sufficiency in operation, maintenance and repair annual costs; to deliver water by volume in irrigation plots and establish a water quota per hectare in accordance with resource availability and crop patterns; and to promote higher recovery of the public investment in infrastructure systems. If the method that has been devised is put into practice, the price of water for irrigation will be a powerful tool for improving the undesirable conditions which presently exist. It will also help in intermediate and long-term planning, and in deciding on the best allocation of regional water resources among alternative uses and crops. This would lead to better productive patterns in agricultural development. (Baker-FRC)

OPTIMAL WATER PRICING AND STORAGE: THE EFFECT OF DISCOUNTING,
Canterburg Univ., Christchurch (New Zealand). Dept. of Economics.
R. Manning, and D. Gallagher.
Water Resources Research, Vol 18, No 1, p 65-70, February, 1982. 2 Fig, 13 Ref.

Descriptors: *Pricing, *Water storage, *Discount rates, Economic aspects, Elasticity of demand, Optimization, Storage, Water demand, Interest rates.

Work by Riley and Scherer (1979) concerning the relationship of water pricing and storage policies is extended by considering the role of discounting (or time preference) in pricing policy. Optimal storage policies are described by an extension of Hotelling's rule. (1) The price of water in storage must rise with the rate of interest. The rate of water loss from leakage and evaporation may be included. (2) The initial price for stored water is such that the price of water rises enough to equate demand with natural inflow at the moment when contents are exhausted. (3) The price of storage contents must rise at no less than the rate of interest. When storage contents are exhausted the price must not

rise faster than the rate of interest and must eventually fall to a level that makes the next cycle of storage profitable. (4) The smaller the elasticity of demand, the rate of interest, or the longer the planning horizon, the larger the optimal storage capacity. (5) The price of water must increase over the cycle, but the discounted prices must be the same, and the initial price must be set so that the total demand equals total inflow over the cycle. (6) The price of water must increase over the cycle, but the discounted higher price will exceed the discounted lower price. These prices must be set so that at the end of the applicable intervals the storage contents can meet demand in the next period. (Cassar-FRC)

CRISIS-RIDDEN WATER SYSTEMS SHOULD GO PRIVATE,
S. H. Hanke.
Journal of the American Water Works Association, Vol 74, No 2, p 14, February, 1982.

Descriptors: *Economic aspects, Water supply, *Municipal water, Planning, Wastewater treatment, Water demand, Pricing, *Commercial water supply.

Urban water systems are faced with the problem of being unable to raise enough capital to properly maintain and expand their existing systems. The market value of nearly all private water companies is below book value and most municipal systems need repair and renovation. Price controls have caused the capital shortage in the industry. One solution to the capital shortage problem requires a federal subsidy or bail-out program. However, by further politicizing the provision of water a federal subsidy would create great inefficiencies and inequities. A second option involves removing price controls. This would put water purveyors on a self-financing basis in which users would pay the real costs of their water. It would remove the need for water conservation through nonprice rationing programs. Most importantly, it would improve the suppliers' ability to provide adequate, high-quality services. The most desirable way to accomplish price decontrol would be to privatize and deregulate the industry. France has used such a system for many years. (Baker-FRC)

HYDRO-ECONOMIC ANALYSIS AND PROJECTION OF IRRIGATION WATER DEMANDS IN PENNSYLVANIA,
Pennsylvania State Univ., University Park. Inst. for Research on Land and Water Resources.
D. F. Kibler, V. Crowley, R. L. Bartel, W. B. Detar, and E. L. White.
Report, April, 1981. 206 p, 44 Fig, 43 Tab, 66 Ref, 1 Plate, 5 Append.

Descriptors: *Irrigation efficiency, Crop yield, Soil moisture deficiency, *Projections, Model studies, *Water demand, Water stress, Economic justification, Economic yield, Economic prediction, Benefits, Hydrologic data collections, Hydrologic maps, Water allocation, Costs, Irrigation effects, River basins, *Pennsylvania, *Cost analysis.

A 1977 study of Pennsylvania's irrigation needs quantified potential water demands by crop and region by analyzing long-term soil moisture deficit. A more refined estimate of irrigation demand as it is affected by expected net returns to irrigation was desired. The objectives of this study were to: assess economic costs and benefits associated respectively with irrigation system costs and increased crop yield; evaluate new irrigation system and scheduling operations which are energy and water-efficient and that meet moisture-stress levels; project irrigation demand with water availability by DER river basin units; and map irrigable areas and potential water shortages in the DER river basins. A major finding of this study was that irrigation of moderate value cash crops, such as potatoes, is economically justified if irrigation can be applied near the optimal water-stress point for the crop. Net returns on profits will be highest under current economic conditions when higher cash value crops are irrigated with hand-moved, portable set irrigation systems at a trigger point of 0.40 FMD (fraction of moisture deplated). A second major finding involved determining a water shortage index for irrigation, i.e., the maximum acreage that can be irrigated under optimum conditions without depleting water supplies below the 2-year, 30-day drought level. A daily soil moisture model was used to compute moisture deficit in the crop rooting zone on a daily basis over the growing season. The model was then used to compute a seasonal water stress index (WSI). Yield increases above the no-irrigation policy were simulated for certain crops for the years 1948-1975. (Atkins-Omniplan)

BILLING DATA AIDS UTILITY PLANNING,
Arlington County Dept. of Public Works, VA. Public Works Planning.
N. K. Hook, Jr.
Water/Engineering and Management, Vol 129, No 3, p 42, 44, March, 1982. 1 Fig.

Descriptors: *Utilities, *Management planning, *Water demand, Pricing, Prices, Economic aspects, Computers.

A new utility billing system was developed in the early part of 1979 for Arlington County, Virginia, in response to the Industrial Cost Recovery requirements defined in Public Law 92-500. An interactive system with many more capabilities than the older computer assisted operation was put into use. The new system improves the responsiveness for assisting the customer with inquiries concerning the account; provides adjustments to the account; undertakes immediate updates to basic account data needed by customers moving, meter changes or other actions; issues bills within days rather than months due to improvements being made in meter reading procedures and data entry; and permits immediate access to all customer information, thereby minimizing manual research. Currently the county has eight major water pressure zones or service areas. To allow for future flexibility in the system, a two digit code was used, with the first digit describing the pressure zone and the second digit left as a zero for future use. A third numeric code describes the geographic sanitary sewershed. The Refuse Code describes refuse services provided to the account and facilities planning for refuse collection. Many utility systems currently have a billing system which may be capable of providing sophisticated data for use in utility planning purposes. If a new billing system is contemplated, incorporation of such a data base is cost effective in terms of information which will be needed at some future date. (Baker-FRC)

PRICE OR PERSUASION,
Idaho Univ., Moscow. Dept. of Economics.
J. T. Wenders.
Water/Engineering and Management, Vol 129, No 3, p 32-34 March, 1982. 2 Fig, 2 Tab.

Descriptors: *Pricing, *Water demand, Water supply, Water conservation, Economic aspects, Tucson, Arizona.

Events occurring in Tucson, Arizona during the 1970's provided an opportunity to investigate the potentials of two methods of controlling water consumption. The first method considered raising the price as a stimulant to conservation. The second method relies on persuading the consumers to consume less. In Tucson, significant price increases and publicity campaigns were both instituted to encourage water conservation during this period of time. Analysis of the results suggests that the decrease in water usage occurred in response to the price increase and that any decrease in response to persuasion was negligible. However, a Beat-the-Peak campaign aimed at reducing the use of water during the hottest periods of the day has achieved a 20% reduction in water consumption during these times. Even so the separate effect of the Beat-the-Peak program on water consumption was small and was clearly superseded by the effect of the price increase. (Baker-FRC)

CURRENT TRENDS IN COST OF SERVICE STUDIES,
Coffin and Richardson, Boston, MA.
V. F. Pennacchio.
Journal of the New England Water Works Association, Vol 96, No 1, p 55-60, 1982.

Descriptors: *Water rates, *Water costs, *Prices, Water meters, Marginal costs, Cost allocation, Peak demand, Water conservation, Subsidies, Utilities.

Several methods of determining water rates are described. In general the current trend appears to be toward the proven methods of the 1960's and early 1970's. These include the American Water Works Association Base-Extra Capacity Method, which sells no water at less than base cost and charges more for excess demands. If properly designed, this type of structure will result in fair and equitable rates for all customers. Some of the newer concepts in water rates are evaluated. Most marginal cost pricing theories as applied to utilities are actually incremental cost approaches and include long run costs. Problems with these methods are a difference between actual costs and the revenues computed, as well as difficulties in assuming that price is elastic when in fact domestic water prices are nearly inelastic. Demand-type rates (time-of-day metering, peak demand metering, and ratchet rates) can be fair, but recording consumption on a continuous basis is not economically feasible except for very large users. Some of these methods can also encourage heavy use and resultant increased sewage flows during off-season of off-peak hours. Although conservation-type rates, which penalize large users, discourage waste, they can also discourage industrial growth. Lifeline rates are intended to establish a low subsidized rate for a minimum quantity of service to help low income families. This is not fair because low quantity users, whether affluent or poor or on vacation, will receive the subsidy. (Cassar-FRC)

COLORADO RIVER WATER ALLOCATION,
Colorado River Board of California, Los Angeles.
M. B. Holburt.
Water Supply and Management, Vol 6, No 1-2, p 63-73, 1982. 5 Tab.

Descriptors: *River basin development, *Water rights, *Water supply development, *Colorado River, *Water law, *Salinity, Water resources development, River basins, River systems, Potential water supply, Available water, Riparian rights, Water quality control.

The states drained by the Colorado River System have tried to obtain for their citizens maximum use of the water resources from the river. The water supplies of this system are already 90% utilized, with full use of Colorado River waters expected within the 1980's. The 'Law of the River', which controls the apportioning of river waters, is composed of many interstate compacts, federal laws, water delivery contracts, state legislation, a treaty and other agreements with Republic of Mexico, a United States Supreme Court decision and federal

USDA-NAL, Ft. Collins, Colorado

administrative actions. By 1990, total water uses are expected to reach the dependable annual flow of 14 million acre feet. Since this figure is not as great as anticipated when the waters were apportioned, there is potential for serious future conflicts. Future water resource development projects will need to concentrate on meeting the obligations of the Mexican Water Treaty of 1973. Several salinity control measures must be enforced to ensure the quality of Colorado River water for Mexican and United States users as well. (Geiger-FRC)

6D. Water Demand

A NEW LOOK AT SMALL POWER PLANTS. 2. THE ENVIRONMENTAL EFFECTS,
California Univ., Berkeley.
D, B. Champion, and M. D. Williams.
Environment, Vol 22, No 3, p 25--32, April, 1980. 3 Fig, 2 Tab, 8 Ref.

Descriptors: *Environmental effects, *Powerplants, Electric powerplants, Water demand, Water supply, Water pollution, Water rights, *Comparison studies.

The Los Alamos Scientific Laboratory has conducted a study comparing the use of small coal-fired power plants with the use of large power plants for expanding electrical generating capacity in the Rocky Mountain West. The environmental aspects of constructing one 3000 megawatt power plant were compared with the environmental effects of three 500 megawatt and one 750 megawatt units; all units considered were proposed for construction in southeastern Utah. Water supply availability poses a significant problem in the construction of any coal-fired power plants, since in many cases the available supply is already fully used. Small plants would be more easily able to assemble the rights to surface water supplies by purchasing them from irrigators than would large plants. In either case, transferring water from irrigation to use by the power plants would have the beneficial effect of reducing irrigation return flows in the Colorado-Green River basin and salinity in the rivers. Since the power plants do not discharge waste water back to the rivers, no other significant water quality impacts would occur. It is concluded that although the cumulative impact of a series of smaller power plants might equal that of a large plant, the impact would be spread over a larger area and would therefore be more easily absorbed by the environment. COMPETITION FOR WATER RESOURCES: COAL AND AGRICULTURE IN THE YELLOWSTONE BASIN,
Indiana Univ. at Bloomington.
T. D. Georgianna, and K. E. Haynes.
Economic Geography, Vol 57, No 3, p 225-237, July, 1981. 3 Fig, 3 Tab, 17 Ref.

Descriptors: *Water demand, *Forecasting, *Competing use, Water management, Resources management, Mathematical models, Optimization, Agriculture, Coal mining, Montana, *Yellowstone River basin.

The Yellowstone River Basin serves as an archtypical system in which to assess the competing demands made upon water resources by energy and agriculture. One method currently used for forecasting water demand in strip mining operations plots the relationship between water use in coal production and the amount of coal produced to approximate straight-line time series forecast. However, major assumptions underlying this methodology are shown to be false. An alternative scheme is presented which takes advantage of shadow pricing, permitting the formulation of a non-linear mathematical programming problem for the derivation of an optimal solution to the allocation of a limited resource among competing users. This formulation for minimizing the cost of water in an area where agriculture and coal production are in competition for limited water resources provides a workable formulation which yields information about the relationship between water uses in the two industries and about costs of water as incentives or disincentives for pollution. (Carroll-FRC)

NET ENERGY: RESULTS FOR SMALL-SCALE HYDROELECTRIC POWER AND SUMMARY OF EXISTING ANALYSES,
Energy Policy Studies, Inc., Omaha, NE.
M. W. Gilliland, J. M. Klopatek, and S. G. Hildebrand.
Energy, Vol 6, No 10, p 1029-1040, October, 1981. 7 Tab, 25 Ref.

Descriptors: *Powerplants, *Hydroelectric plants, *Economic efficiency, Energy conversion, Performance evaluation, *Dams, Retrofitting.

Net energy analysis is a potential tool for evaluating emerging energy technologies. A net energy analysis was performed for small scale hydroelectric power facilities to permit comparison with conventional hydroelectric plants and other technologies. The analysis was applied to seven projects based on retrofitting of existing dams, with powerplant capacities ranging from 1325 to 6500 kw. Unit capital costs ranged from $432 to $1488 per installed kw. Most of the power plants were to operate as run-of-the river facilities. Energy inputs were calculated as the sum of all primary energy required to construct and operate the plant. The net energy ratios of five of the seven facilities were remarkably consistent at 10-12:1. Thus the majority of small-scale hydroelectric retrofits should deliver 10-12 times more energy as electricity and 31-37 times more energy as fossil fuel equivalents than is required to build and operate them. Results were compared with conventional hydroelectric plants with capacities at least an order of magnitude larger than the small facilities. Net energy ratios for peak power dams were smaller than those for the small hydro facilities, while the ratio for the base-load examined was similar to the mean for the small-scale hydro facilities. These findings support the concept that substantial energy savings can be realized by making investments in retrofit of existing capital stocks. (Carroll-FRC)

WATER SUPPLY IN THE USSR.
Water Services, Vol 85, No 1029, p 568-569, 1981.

Descriptors: *Water supply development, *Water demand, *Potable water, Drinking water, Water supply, Water quality management, Water management, Water use, Consumptive use, Moscow, *USSR.

The 1981 to 1990 decade was declared the International Drinking Water Supply and Sanitation Decade by the UN General Assembly. Each individual in Moscow, on the average, consumes almost 700 liters of potable water daily. Most of the Soviet Union's freshwater flows to the Arctic Ocean and the Pacific in the scarcely populated areas of the country. The Soviet State Standard sets stringent demands on drinking water purity. Muscovities pay for part of the water they use, while the rest of the expenses are covered by the city's enterprises. Water supplies are fluorinated to comply with USSR legislation. Freshwater consumption is increasing rapidly and its use by factories is being restricted in some places. In deciding upon prices for water supply, the republican and local authorities are invariably trying to keep prices for household use as low as possible. Many establishments in the Soviet Union are studying the problems of water supply while the Main department of Water Protection of the USSR Ministry of Land Amelioration and Water Economy and local governments protect surface and underground water supplies. A new plan set forth in the Protection of the Environment section of the Guidelines for the Economic and Social Development of the USSR for 1981-1985 and for the Period Ending in 1990 intends to expand to use of recycled water, introduce more non-effluent closed-water circuits, and adopt water protection projects more quickly. (Geiger-FRC)

FRESH-WATER TRANSPORT BY SEA,
Oufresne and Henry Engineers, Inc., North Springfield, VT.
R. M. Dunlap.
Journal of Hydrology, Vol 51, No 1-4, p 313-318, May, 1981. 1 Fig, 4 Tab, 3 Ref.

Descriptors: *Water transport, *Ships, *Transportation, Water supply, Arid lands, *Icebergs.

Researchers have recently begun to study the feasibility of transporting icebergs to help meet the water needs of arid lands. As an alternative, it is suggested that a submerged, flexible water container pulled by a semi-submerged tug boat could be used to transport fresh water from regions of abundant fresh water or from the mouths of such rivers as the Amazon and the Rhone to arid lands accessible by sea transport. This sea transport system is composed of the container and its ballast, the tug and a tow cable, and the terminals. The proposed container is a non-circular flexible cylinder fabricated of multilayer polyester sheet and having the cross-sectional shape of a fish. This fresh-water container would have a capacity of 5,000,00 cubic meters. The specially-designed low-speed, semi-submerged, highly-efficient diesel-powered twin screw tug boat would pull the container with a commercially available nylon cable. Upon arrival at its destination, the container would be anchored and secured and connected to the water distribution system, serving as a reservoir for the fresh water. Several potential transport routes, ranging from 900 to 4.700 kilometers, are suggested. Total capital costs are estimated to be $50,650,000. The total transport cost is estimated at about $0.03 per ton per 1,000 kilometers. (Carroll-FRC)

STRIPMINING ARID NAVAJO LANDS IN THE US: THREATS TO HEALTH AND HERITAGE,
J. Radford.
Ambio, Vol 11, No 1, p 9-14, 1982. 4 Fig, 1 Tab, 29 Ref.

Descriptors: *Strip mines, *Water supply, Environmental protection, Water rights, Aquifers, Water quality, Water reuse, *Water demand, *Chaco region, *New Mexico.

Massive strip mining operations in the Chaco region of New Mexico's San Juan Basin may accelerate desertification, deplete already scarce water supplies, undermine the Navajo Indian way of life, dramatically degrade air quality, and compromise fossil and archeological resources of world importance. With an average precipatation of 9 inches or less, the Chaco is the most arid of the 12 national coal production regions designated by the US Department of Energy. The scarcity of water has important implications for the land's reclamation potential after stripmining, although current laws require that stripmined land be returned to its previous productive capacity or better. Total precipitation in the form of snow averages only 1.82 inches during a typical winter. Under certain conditions snow fences could help protect seeded areas from the Chaco's strong winds, but in any event this is considered a very expensive method

for widespread usage. Surface water and shallow aquifers cannot begin to meet the expected water demand in this area of the country. Alternative sources being considered include diverting water about 40 miles from the San Juan River to the north, drilling deep wells at numerous locations in the Chaco, and re-using water pumped out of uranium mines to the south. Use of the river water is highly contested, with the Native Americans claiming that their treaty rights to water are already abridged by over-allocations. (Baker-FRC)

WATER USE IN OHIO, 1975,
Geological Survey, Columbus, OH. Water Resources Div.
R. M. Hathaway, and M. Eberle.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-192980, Price codes: A03 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-17, 1981. 43 p, 6 fig, 7 Tab, 41 Ref.

Descriptors: *Water use, *Water supply, Surface water, Groundwater, Thermal powerplants, Industrial water, Municipal water, Livestock, Irrigation water, *Ohio, Water demand.

The estimated water use in Ohio for all purposes in 1975 was 16,431 million gallons per day. Of this total, 15,321 were taken from surface water while the remaining 1,110 represent ground-water withdrawals. Totals by category are as follows (in million gallons per day): Thermoelectric power generation, 12,404; self-supplied industrial use, 2,362: public water supplies, 1,423; rural domestic and livestock, 201; and irrigation, 40. Per capita water use was calculated to be 1,528 gallons per day for an Ohio population of 10,751,000 in 1975. Jefferson County led all Ohio counties in total water use with 3,447 million gallons per day. This was nearly three times the usage of second-ranking Gallia County where withdrawals were 1,242 million gallons per day. The heavy water use in both of these Ohio River counties is due to large withdrawals for thermoelectic power generation. Cuyahoga, Lorain, and Lake Counties, all in the Cleveland metropolitan area, rank third, fourth, and fifth in the State with respective totals of 1,061, 1,047, and 1,030 million gallons per day. Water use is more diverse in this area, with public supplies, industrial use, and thermoelectric power all making significant impacts. (USGS)

RIVER BASINS AND WATER MANAGEMENT IN NEW BRUNSWICK,
New Brunswick Dept. of Fisheries and Environment, Fredericton.
W. F. G. Cardy.
Canadian Water Resources Journal, Vol 6, No 4, p 66-79, 1981. 1 Fig, 3 Ref.

Descriptors: *Water management, *Planning, *New Brunswick, Water pollution control, River basins, Public participation, Administration, *Water policy, St. John River, Water resources development, Canada.

New Brunswick has abundant water, a small population, and little perceived need for water management. Sufficient water is available for use as well as for wastewater dilution in the river basins, but the coastal plains using limited groundwater are experiencing occasional shortages. Management activities have generally been on a provincial scale. A major planning exercise took place in the St. Johns River Basin during 1970-74. Comprehensive reports and 30 specialist reports were issued. A framework for water management with eight levels of decision was established. Implementation of the plan has been slow for three reasons: (1) the question of whether a comprehensive study was necessary when the major pollution arose from only a few well-identified sources, (2) changes were not suggested, but people were encouraged to find the solution themselves, and (3) loose administration and changing governmental policies. The study did, however, arouse public interest and discussion about the pollution problems. At present there is no need for further basin-wide planning in New Brunswick. Strategy should be directed toward solving problems on the local level as the needs arise. (Cassar-FRC)

COLD LAKE-BEAVER RIVER REGIONAL WATER RESOURCES STUDY,
Department of the Environment (Edmonton).
B. MacLock, and R. Hicks.
Canadian Water Resources Journal, Vol 6, No 4, p 119-140, 1981. 3 Fig, 1 Tab, 12 Ref.

Descriptors: *Oil shale, *Water demand, *Water management, *Planning, *Alberta, Cold lakes, Beaver River, Water pollution sources, Water use, Water quality, Decision making, Water resources development, River basins, Water allocation, Canada.

The Cold Lake-Beaver River Regional Resources Study was initiated in 1980 to develop a framework plan for the long-term management of the region's water resources. Within these basins are both vast oil sands deposits, extractable only by in situ mining, and a large percentage of the province's recreation and fishing lakes. Potential conflicts exist between these two uses. Specific study objectives were developed as part of a framework plan for long-term water management. From the objectives was formulated a study framework with 10 components: management issues, water supply (quantity, quality, and groundwater), water use, legal aspects, modelling, goals, management alternatives, public participation, synthesis and evaluation and plan formulation. Some of the obstacles in meeting the study objectives are: limited hydrometric and atmospheric data, uncertain water withdrawal forecasts for oil sands development, and lack of data in the instream fisheries field. The study will be undertaken in 4 phases over a 3.5 year period. (Cassar-FRC)

THE INTERACTION BETWEEN WATER SCARCITY AND WATER QUALITY DEGRADATION: ISRAEL AS A CASE STUDY,
Hadassah Medical School, Jerusalem (Israel). Environmental Health Lab.
H. I. Shuval.
Water Science and Technology, Vol 14, No 1/2, p 453-463, 1982. 3 Fig, 5 Tab.

Descriptors: *Water management, *Water policy, *Water scarcity, *Israel, Desalination, Political aspects, Chlorides, Nitrates, Planning, Water reuse, Agriculture, Irrigation, Saline water intrusion, Eutrophication, Water shortage, Lake Kinneret, Semiarid lands, Water consumption, Wastewater irrigation, *Water demand, Coastal aquifers, Aquifers, Groundwater.

Israel is faced with severe water shortages and increasing degradation of water quality. Actual water consumption in 1981 was 1700 million cu m, using all the 1500 million cu m per year of replenishable fresh water and 200 million cu m per year of reused, brackish water or unreplenishable groundwater. By 2000 there may be a gap between demand and supply of 500 million cu m per yeat. About 25% of Israel's water resources are threatened by saline water instrusion into the coastal aquifer. The most effective remedy is reducing groundwater exploitation by half. Other schemes, diversion of Lake Kinneret water and shifting the site of groundwater exploitation, only delay the harmful effects for another generation to handle. Nitrates derived from human sources, have been increasing in water supplies at the rate of 1.35 mg per year. An effective strategy to combat nitrate pollution is 50% reduction in fertilizer application, tertiary treatment of all wastewater used for agricultural irrigation, and temporary groundwater recharge and exchange. Although wastewater reuse can help alleviate water scarcity problems, it causes its own difficulties--a burden of toxic chemicals and pathogens and disposal of effluents during the non-irrigation period. A practical scheme is to recycle treated wastewater for agricultural and industrial use, saving the highest quality water for domestic use. Desalination of seawater, included in many forecasts for 2000, is not economically feasible. (Cassar-FRC)

INTEGRATED WATER MANAGEMENT: SOME INTERNATIONAL DIMENSIONS,
Biswas and Associates, Ltd., Ottawa (Ontario).
A. K. Biswas.
Journal of Hydrology, Vol 51, No 1-4, p 369-379, May, 1981. 6 Tab.

Descriptors: *Water management, *Water supply development, Resources management, Social aspects, Environmental policy, Projections, Hydroelectric power, Agriculture, Developing Countries.

The continuing increase in world population and the rising standard of living throughout the world will result in demands for more and more water supplies to meet basic human needs. The global picture with respect to water use and availability is very uneven. A 1976 survey of developing countries showed that only 35% of the people in these countries had adequate water supply and sewerage services. In the rural areas of many countries, less than 5% of the people have access to safe water. Water is essential for agriculture, and the total area under irrigation must be increased if the world food crisis is to be solved. In addition, better use must be made of irrigation water. Industry is a major user of water resources. In the United States, industrial demand accounts for about 40% of total water requirements. In addition, industrial users discharge large amounts of industrial wastes to water systems. The effects of expanding industrial development in third world countries on water resources will depend on the availability of water supplies and on water quality and wastewater regulations set by these countries. While hydropower resources have been extensively developed in North America and Europe, there is a vast, unexploited potential in Africa, Asia, and Latin America. More attention needs to be focussed on the social and environmental implications of water development, particularly in developing countries. It is concluded that the question of the availability of adequate water to sustain future world population and development over the next two decades is primarily one of instituting rational management practice. (Carroll-FRC)

COSTA RICA STAYS TOP OF WATER LEAGUE,
World Water, Vol 5, No 2, p 14-15, February, 1982. 5 Fig.

Descriptors: *Water resources development, *Water demand, Costa Rica, Latin America,

Water supply, Reservoirs, Wastewater treatment, Drinking water.

Costa Rica is well ahead of other Latin American countries in terms of water supply and waste disposal, with 98% of the urban population receiving safe water and 61% in rural areas. For waste disposal, systems are available to 96% of the urban population and 86% of the country dwellers, although many of them involve discharge of untreated wastes into the rivers. The modern story began with the foundation of the Instituto Costarricense de Acuaductos y Alcantarillados (AyA) to deal with a water crisis at the beginning of the 1960s which greq out of the inabilities of individual municipalities making up the city and environs to cope with growing demands. AyA devoted most of its first 20 years to the task of establishing its own organization and providing for the various systems that had previously supplied districts in the capital and other areas. Large portions of the national budget were channeled into sanitation and water supply. The recently completed second phase of the AyA operations has been the replacement of much of the old network in the San Jose area and construction of certain key elements in the overall scheme after emergency work and a chlorine injection and pumping plant at Puente de Mulas and distribution systems for the whole area. With the effective completion of Phase 2 of the supply plan, AyA sought and secured from the British government assistance in the preparation of a mathematical model to determine the overall efficiency of the system to provide data for progress on Phase 3. A mathematical model is being devised which can be updated to grow with the progression of additional networks and the improvement of existing ones. (Baker-FRC)

THE NILE WATERS: SUDAN'S CRITICAL RESOURCE, PART II,
Edinburgh Univ. (Scotland). Dept. of Electrical Engineering.
H. Dickinson, and K. F. Wedgwood.
International Water Power and Dam Construction, Vol 34, No 2, p 31-34, February, 1982. 24 Ref.

Descriptors: *Water resources development, *Planning, Sudan, Irrigation, Agriculture, Jonglei project, Nile River, Dams.

Major dams on the Blue Nile and the Atbara have succeeded in making better use of what were formerly seasonal waters, but the ecological impact of the Roseires dam has yet to be fully evaluated. The 1959 Nile Waters Agreement has been of benefit to Sudan, as has the development of rain-fed and underground-water-fed agriculture which play an important role in that country. However, the quantity of water from these later sources is small in relation to the contribution of the Nile river system. The growth of agriculture based on irrigation in Sudan is likely to be restricted by the provisions of the Nile Waters Agreement. Its cost is high and the risks involved in reducing the water entering the Sudd are also to be considered. To minimize these risks an extensive research program has been undertaken. Much of the environmental and ecological work is directed toward filed surveys, and the data collected will provide valuable base material against which the effects of the Jonglei canal may be judged. The energy-intensive desalination of water taken from the Red Sea is an option open to Sudan only if major oil finds should occur in the country. At present, therefore, even if the Jonglei project is successful in providing Sudan with a further annual supply of 3 or 4 billion cubic meters of water, it will only delay the time when further conventional agricultural development will be impossible without new water resources. (Baker-FRC)

LARGE WATER AND HYDROELECTRIC DEVELOPMENTS IN FIJI,
H. Bandler.
Search, Vol 13, No 1/2, p 26-30, February/March, 1982. 7 Fig, 1 Tab, 2 Ref.

Descriptors: *Water resources development, *Construction, Dams, Fiji Islands, Economic aspects, Powerplants, Hydroelectric plants, Hydroelectric power.

The construction of Vaturu Dam and the associated works of the Nadi and Lautoka Regional Water Supply Scheme will supply high quality drinking water to a great number of Fijians and their visitors. The Monasavu-Wailoa Power Project will save the country millions of dollars with its integrated power grid and the generation of hydroelectric power. Both of these large, complex projects will assist in making the country self-reliant. Carried out in situations where great natural obstacles were encountered, they are technical achievements in which expertise and knowledge has been gained which will facilitate further development of the water resources of Fiji. The dams are leading examples of modern construction. Although expatriate engineering staff is largely involved, considerable local skill has been demonstrated by technical and professional employees. The hydroelectric plant will significantly reduce the need for imported oil. (Baker-FRC)

WATER SUPPLY FOR NEW YORK CITY IN THE 1980S,
Olympia and York Battery Park Co., New York.
F. X. McArdle.
Journal of the American Water Works Association, Vol 74, No 3, p 137-139, March, 1982.

Descriptors: *Water supply, *Urban areas, *Water management,*New York City, Water quality, Water distribution, Financng Reliability, Metropolitan water management, Water treatment, Water demand, Water consumption, Capital costs, Maintenance, Drinking water, Drought.

New York City's water system faces problems of providing sufficient quantities, maintaining high quality, ensuring reliability of supply, and financing capital needs. Although the city's population has not grown, water demand has increased with the installation of more air conditioning and home appliances. It is unknown whether demands will continue to increase, in which case new water sources must be sought. In the short term, droughts will periodically force reductions in consumption. The lack of widespread metering in the city is a hindrance in water management during a period of shortage. New York's protected watersheds have provided raw water requiring only disinfection, fluoride, and algae control. Increased development in Westchester and Putnam counties necessitated construction of a $250 million filtration plant in the Croton system. Another water quality issue involves the use and disposal of toxic chemicals within the watersheds. To ensure reliability of the main system over $100 million must be spent in the next 10 years to maintain dams properly. A third water tunnel is expected to reach completion by 1990. The 10,720 km distribution system suffers from frequent breaks, at least two major ones per day. Most failures are a result of disturbances by traffic and subways. A 3-year program is designed to replace 38 km of Manhattan's 150 mm pipe to reduce breaks by 20% per year. Financing replacement and new facilities is difficult for large, older cities. It is hoped that the present capital replacement program can be maintained over the long term in spite of institutional strictures imposed by the state constitution. Unless the cities solve problems of quantity, quality, reliability, and financing in their drinking water system they face continual decline and disintegration. (Cassar-FRC)

COMPARING TWO MEASURES OF WATER BASED RECREATION PARTICIPATION,
Wisconsin Univ.-Madison. Dept. of Forestry.
J. H. Gramann, and R. J. Burdge.
Water Resources Bulletin, Vol 18, No 2, p 339-341, April, 1982. 1 Tab, 4 Ref.

Descriptors: *Recreation, *Surveys, *Public participation, Lakes, Boating, Fishing, Public waters, Swimming, Fishing.

Two methods of measuring participation at water based recreation sites were compared at Lake Shelbyville, Illinois. Respondents were asked to name the main recreation activity in which they participated at the reservoir during an entry point interview and then by a questionnaire mailed to the home. The percentages of persons specifying the same main activity in both types of surveys were: boat fishing, 91.4; water skiing, 81.0; shore fishing, 74.0; power boating, 65.3; swimming, 60.4; and relaxing, 37.5. Inconsistencies were most common in activities which overlapped (power boating, water skiing, and boat fishing) and in generalized activities (relaxing). In general either method or combinations of both methods can provide reasonably unbiased measures of water based recreational use. (Cassar-FRC)

MODELING OF WATER SUPPLY/DEMAND IN THE SOUTH PLATTE RIVER BASIN, 1970-2020,
Colorado State Univ., Fort Collins. Engineering Research Center.
D. W. Hendricks, B. A. Janonis, S. Gerlek, J. C. Goldbach, and J. L. Patterson.
Water Resources Bulletin, Vol 18, No 2, p 279-287, April, 1982. 5 Fig, 2 Tab, 10 Ref.

Descriptors: *Water supply, *Water demand, *Hydrologic budget, South Platte River Basin, *Colorado, Model studies, Water conservation, Planning, Long-term planning, Systems analysis, Water storage, Forecasting, Drought, Irrigation, Water reuse, Water transfer.

A water balance model was applied to the South Platte River Basin, Colorado, to determine solutions to the supply/demand problem for both average andd stress conditions for the years 1980, 2000, and 2020. The base year was 1970. The model was displayed in tabular form on 8ft x 8ft color-coded magnetic board. Solutions obtained for different conditions were produced for evalution by different interest groups. Some of the information obtained from this model as applied to the South Platte Basin included: the present per capita water use of 220 gpcd could be reduced to 167 gpcd without severe difficulties, an additional 280,000 acre feet could be imported from the Colorado River basin with minimum social and economic disruption, the potential role of large-scale water exchanges between urban and agricultural users should be explored, water reuse is necessary, irrigated acreage can be adjusted to the amount of available water, and increased storage facilities would capture excess flows. (Cassar-FRC)

DEVELOPMENT ISSUES IN THE COLORADO RIVER BASIN,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
G. V. Skogerboe.
Water Supply and Management, Vol 6, No 1-2, p 3-10, 1982.

Descriptors: *Water rights, *Colorado River, *Water resources development, *Water supply de-

velopment, *Water allocation, *Irrigation practices, River basins, Water management, Resources management, Irrigation water, Irrigation-return flow, Available water, Salinity.

An overview of the historical settlement of the Colorado River Basin, its economic growth and water and energy development, and prospects for meeting future resource needs is presented. Mexico is already using its full entitlement of water from the river, while the Lower Basin will reach its maximum allowable usage in just a few years with the completion of the Central Arizona Project in the 1980's. The upper Basin has developed about two-thirds of its entitlement and must make many serious water allocation decisions before full development. Energy development and allocation of water to adjoining basins for urban growth are major considerations in the Upper Colorado River Basin. The Lower Basin is facing similar problems as its population increases. Salinity levels must be kept to a minimum to ensure maximum utility of available water supplies. This is done most effectively by on-farm irrigation projects. Water rights decisions for Indian reservations will play a significant role in the future development of the Colorado River Basin. (Geiger-FRC)
W82-05890

THE PHYSICAL ENVIRONMENT OF THE COLORADO RIVER BASIN,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
G. V. Skogerboe.
Water Supply and Management, Vol 6, No 1-2, p 11-27, 1982. 6 Fig, 1 Tab, 13 Ref.

Descriptors: *Water resources development, *Water supply development, *Colorado River, *Available water, *Resource development, *Groundwater mining, Water management, Groundwater management, Water use, Irrigation water, Recreation, Coal mining, Groundwater recharge, Land use, Geomorphology, Climates.

Some of the physical features, climatic conditions, water resources, land use, and scenic and recreational resources of the Upper and Lower Colorado River Basin are examined along the energy resource developments along this river basin. Water supplies of the basin are utilized heavily; about 30% of the water supply is exported to adjoining basins to serve primarily metropolitan areas. Approximately 15 million acre-feet of water originate in the Upper Basin, while 3 million acre-feet come from the Lower Basin. The Lower Basin states are now using nearly all of their entitlement to surface water supplies from the basin and mining groundwater for municipal, agricultural and industrial use at a rate faster than natural recharge rates. States of the Upper Colorado Basin have not fully utilized their entitlement and mine groundwater principally for industrial and municipal use. About 50% of the potential hydroelectric power of the basin has already been developed. The mining of uranium, coal, and shale oil in the Colorado basin will also create new water needs. (Geiger-FRC)

6E. Water Law and Institutions

TOWN OF DE BEQUE V. ENEWOLD: CONDITIONAL WATER RIGHTS AND SATUTORY WATER LAW,
M. Hope.
Denver Law Journal, Vol 58, No 4, p 837-845, 1981. 78 Ref.

Descriptors: *Water rights, *Water law, *Colorado, *State jurisdiction, Water management, Water allocation, Legal aspects, Land rights, Land tenure, Appripriation, Water use.

In the past history of Colorado water law, an opposing party bore the onus of challenging a conditional water right in court. As a result of the decisions of De Beque vs. Enewold and other recent water rights cases of the Colorado Supreme Court, the burden of successfully maintaining a conditional water right through strict compliance with the statute is now upon the holder. A conditional water right may expire after a certain lapse of time under section 37-92-301 of the Colorado Water Rights Determination Act of 1969 if the holder does not obtrain and file an application for a reasonable finding of beneficial use of the water as required by section 37-92-601 of the law. In 1975, an amendment to the 1969 Water Act, section 37-92--305, alleviated some of the pressure on the holder by requiring the court to give notice prior to the cancellation or expiration of a conditional water right. The significance of the decision, however, lies beyond the holding of the De Beque case, which exemplified strict interpretation of statutory water law and the court's deference to the lawmaking function of the general assembly. (Geiger-FRC)

BRYANT V. YELLEN: PERFECTED RIGHTS ACQUIRE NEW STATUS UNDER A BELATED CLARIFICATION OF ARIZONA V. CALIFORNIA,
J. D. Carver, and C. L. Kramlich.
Denver Law journal, Vol 58, No 4, p 847-860, 1981. 137 Ref.

Descriptors: *Water rights, *Irrigation districts, *Land tenure, *Reclaimed water, *Legal aspects, Water law, Irrigation water, State jurisdiction, Water allocation, Water reuse, Reclamation, Water use, Water demand, *Imperial Valley, California, Arizona.

The Federal Reclamation Act of 1902 states that single owner land holdings of 160 acres or less are ineligible for the delivery of reclamation water for irrigation purposes. This restriction and a residency requirement were included in the law to promote widespread land ownership and a more equitable distribution of federal benefits. Section 46 of the 1926 Omnibus Adjustment Act empowers the Secretary of the Interior to deny water to any landowner who refuses to dispose of his land in excess of 160 acres. In 1929, the Boulder Canyon Project Act was drawn up to allow the Imperial Valley to receive water from a reclamation project. In 1932, the Imperial Dam and All-American Canal were constructed. Some landowners in the Imperial Valley with vested water rights were declared immune from the 160-acre limitation law by the Project Act. The Bryant vs. Yellen court case signaled a change in the Supreme Court's position toward resolving conflicts between federal and state law over the delivery of reclamation water. By upholding the present perfected water rights, the court managed to avoid the controversial issue of reclamation policy which might be better addressed by Congress. (Geiger-FRC)

OIL SHALE AND WATER QUALITY: THE COLORADO PHOSPECTUS UNDER FEDERAL, STATE, AND INTERNATIONAL LAW,
Denver Univ., CO.
P. S. Dempsey.
Denver Law Journal, Vol 58, No 4, p 715-749, 1981. 244 Ref.

Descriptors: *Oil shale, *Legal aspects, Resources development, Water law, Legal review, Legislation, Water pollution, Environmental protection, *Water pollution control, *Colorado.

This article reviews the different levels of water pollution regulations and explores whether the United States' domestic oil shale reserves can be developed in a manner that not only promotes national energy policy but also accords with national environmental policy. An overview of the potential for water pollution associated with oil shale development is offered. The Federal regulatory scheme is discussed with emphasis on the federal water pollution contol act, including the National Pollutant Discharge limination System (NPDES) permit program and the dredge or fill permit program; the resource conservation and recovery act, including the hazardous waste management program and the solid waste disposal program; the safe drinking water act; and the effect of a federal permit. The Colorado Regulatory Scheme is discussed, including the state administration of the NPDES, RCRA, UIC, and section 404 programs; water quality protection via other means; water quality regulation and water rights; and federal preemption. The international environmental regime between the United States and Mexico is considered emphasizing the effect of the 1944 treaty between the countries in that the treaty does not specifically address water quality but does implicitly address it. The conventional and customary legal regimes are considered including the effect of United States Federal Precedent, International precedent, and the effect of customary international law. NON-INDIAN FEDERAL RESERVED WATER RIGHTS,
Hall and Evans, Denver, CO.
S. L. Waring, and K. S. Samelson.
Denver Law Journal, Vol 58, No 4, 783-799, 1981. 160 Ref.

Descriptors: *Reservation doctrine, *Water rights, Legal aspects, Water supply, Legal review, Legislation, Water law, Federal jurisdiction, State jurisdiction, Jurisdiction, *Montana.

The purpose of this article is to examine the extension of the Winters doctrine to non-Indian federal reservations and to consider some of the legal issues associated with this extension. Under the Winters doctrine, the United States Supreme Court determined that acquisition of the water rights for the Fort Balknap Indian Reservation was not governed by state law. Various types of Federal reservations and their sources of authorization are described, with a discussion of the applicability of the federal reserved water rights doctrine to each reservation. Special attention is given to a 1979 opinion of the Solicitor of the Department of the Interior, as this document represents the most comprehensive statement made by the Solicitor on federal reserved water rights. Recent trends and developments, however, suggest the declining fortunes of the doctrine of federal reserved water rights concludes. Many of the ambiguities of the reserved water rights doctrine will not be settled until they arise in the context of litigation. Congress has not enacted any legislation dealing explicitly with the reserved water rights doctrine. In contrast to congressional and executive inactivity, the Supreme Court limited the reserved water rights doctrine in the Mimbres decision, wherein the Court's restriction of reserved water rights to the primary purposes for which a particular reservation was originally created occurred even though Congress later enacted legislation expanding the purposes for which the reservation may be administered. This decision may mark the beginning of a trend toward a narrow construction of the reserved water rights doctrine and a step toward state control over water resources. (Baker-FRC)

GROUNDWATER MONITORING,
J. Josephson.
Environmental Science and Technology, Vol 15, No 9, p 993-996, September, 1981. 2 Fig.

Descriptors: *Groundwater, *Monitoring, *Water quality, *Groundwater pollution, *Legislation, Measuring techniques, Water sampling.

It has been predicted that Federal legislation enacted during the last decade will result in the drilling and installation of over one million wells designed to monitor potential sources of groundwater pollution. Samples representative of aquifer conditions should be obtained in such a way that their chemical integrity is preserved to the fullest extent possible. Multilevel point sampling or other multilevel instruments amenable to use with individual positive-displacement pumping systems should be used for sample collection. Filtering and processing of the samples should be conducted in such a way that no volatiles are lost and that no change in pH, metal, or other oxidation-reduction sensitive constituents occurs. Oxygen invasion of

UTAH U. DEPT. OF L. WATER & SCIENCE

the sample must be avoided. A very detailed knowledge of the particular geologic and hydrologic formations and variables involved is essential to groundwater monitoring when the aquifer medium is porous carbonate rock. It may be advisable in many cases to run a geophysical survey to map aquifer size, shape, flow, and composition of the porous and impermeable media prior to the drilling of wells for monitoring. SOME EMERGING RIGHTS IN AGRICULTURAL LAND,
Illinois Univ. at Urbana-Champaign. Dept. of Agricultural Economics.
J. B. Braden.
American Journal of Agricultural Economics, Vol 64, No 1, p 19-27, February, 1982. 36 Ref.

Descriptors: *Pollution control, *Legal aspects, Conservation, Wetlands, Land use, Water use, *Property rights, Economic aspects, Farming, *Agriculture.

A framework is set forth within which present reform efforts for soil conservation, nonpoint pollution control, wetlands protection and farmland preservation may be understood and from which flow implications for changes which are appropriate according to legal and economic criteria can be examined. In general society is well served by the liberal allocation of rights to farmland owners. The costs of monitoring and enforcing other arrangements would be prohibitive. Exceptions to this pattern are likely to occur where relatively little, easily identified land is involved, as with wetlands regulation. Much more change is apparent in the rules governing the exchange of rights. Where a reallocation of rights in response to new problems would be too costly or inconsistent with prevailing judicial sentiments, liability protections are attached to individuals' rights. This provides a mechanism by which the public interest can be served while providing fair compensation to owners whose rights are exchanged by fiat. It retains the flexibility of individual ownership and is consistent with the national ethic of maximum individual liberties consistent with the general welfare. (Baker-FRC)

ARIZONA GROUND-WATER REFORM: INNOVATIONS IN STATE WATER POLICY,
Arizona Univ., Tucson. Dept. of Political Science.
S. Hansen, and F. Marsh.
Ground Water, Vol, 20, No 1, p 67-72, 1982. 15 Ref.

Descriptors: *Water law, *Water policy, *Arizona, *Groundwater management, *Political aspects, *State jurisdiction, Economic aspects, Groundwater mining, Appropriation, Legal aspects, Judicial decisions, Administrative decisions, Water management, Groundwater depletion, Water rights, Policy making.

The major political forces in instituting reforms in Arizona groundwater law are described. Arizona groundwater policy is embodied mainly within the 1980 Groundwater Management Act. This legislation arose from Federal threats affecting a major reclamation project, special interest group pressures resulting from a 1976 decision restricting the transportation of ground water by municipal and industrial users, and the exploitation of groundwater causing dwindling supplies. The reform was achieved through structural decisions which delegated allocative decisions to the special interests directly affected by the ultimate policy. After basic decision costs had been incurred, the initiative was then ratified by the legislature in subsequent legislation without the need for the usual high legislative process costs. A Department of Water Resources was established by the 1980 Act which will be funded by a pump tax in addition to legislative appropriations. The Arizona Groundwater Management Act will only be as strong as it is flexible to handle economic, legal, and political shifts of the state through appropriate amendments in the future. (Geiger-FRC)

ACID RAIN: LEGAL AND POLITICAL FALLOUT,
ERT, Concord, MA.
M. R. Deland.
Environmental Science and Technology, Vol 16, No 1, p 27A, January, 1982.

Descriptors: *Acid rain, *Political aspects, *Legal aspects, Air pollution, Regulations, State jurisdiction, Public rights.

Acid precipitation presents a variety of legal and political problems. Many of the traditional mechanisms for environmental regulation are ineffective in dealing with acid rain, since pollutants originating in one area may result in acid rain in a far distant area which may be in another state, region, or even country. Efforts by the northeastern states to seek redress under the Interstate Pollution Abatement section of the Clean Air Act have met with extended delays within the Environmental Protection Administration. Several states have also filed suit in U.S. Circuit Courts of Appeals. These cases have not yet been resolved. Formal negotiations with Canada regarding acid rain have not resulted in agreement on this matter. A variety of legislative initiatives address acid rain either directly or indirectly and vary significantly in both the limitations on contributing pollutants and the enforcement remedies. There is significant disagreement regarding the effectiveness of the proposed measures in limiting acid rain, and many parties are suggesting further investigations before any action is taken. NATIONAL WATER POLICY: THE NEED FOR INSTITUTIONAL REFORM,
Library of Congress, Washington, DC.
W. Viessman, Jr.
Environmental Management, Vol 6, No 1, p 35-41, January, 1982. 13 Ref.

Descriptors: *Water policy, *Resources development, Public policy, *United States, Water resources development.

The importance of modernizing and simplifying the United States' water management program on the national level has been reviewed. Since the early part of this century, over 20 commissions or committees have labored to identify water problems, evaluate the availability of water and consider new directions in water policy. Many of these efforts have been relegated to library shelves, and there is little to show from the work which went into them. This is explained in part by the fact that few of these reports acquired a strong political constituency. One major exception to the rule was the 1069 study by the Senate Select Committee on Water Resources. Only five general recommendations were made by this committee, but most of these saw legislative action. The Water Resources Council, the Office of Water Research and Technology, and the periodic national water resources assessment process are products of the work of that committee. The performance record of the committee was unusually good, due mostly to its Congressional membership which had the political strength to ensure that its findings would receive the attention of the Congress. Effective policy reform is considered urgently needed if this country is to avoid a major water crisis. (Baker-FRC)

IMPACT OF AMERICAN REGULATIONS ON INDUSTRIAL SLUDGE MANAGEMENT,
Metropolitan Sanitary District of Greater Chicago, IL.
C. Lue-Hing, D. Zenz, and D. Lordi.
Effluent and Water Treatment Journal, Vol 21, No 12, p 547-554, December, 1981. 12 Tab, 21 Ref.

Descriptors: *Industrial wastes, *Waste management, *Legal aspects, Political aspects, State jurisdiction, Federal jurisdiction, Wastewater management, Wastewater treatment, *Illinois, Regulations.

Federal, state, and local governments developed a variety of laws and regulations pertaining to the management of industrial waste residuals during the 1970s. Federal regulations pertaining to hazardous waste management and to the management of industrial wastes generally are reviewed. Illinois water pollution control legislation and solid waste management programs are reviewed as an example of state initiatives. Ordinances of the Metropolitan Sanitary District of Greater Chicago are used to illustrate local regulations. The two main sets of Federal regulations affecting industrial wastewaters are the Pretreatment Regulations, which govern the control of industrial wastes introduced into publicly-owned treatment works, and the Hazardous Waste Management System Regulations. Illinois regulates the disposal of industrial wastes through a program which requires the operator of a disposal site to obtain an additional permit for each type of industrial waste accepted and through the special waste hauling manifest program, which permits tracking of industrial wastes from their generation to final disposal by means of a permit and manifest system. The Chicago sanitary district regulates industrial wastes through concentration limits for 14 contaminants and limiting conditions for the discharge of industrial waste to the sanitary sewer system. Implementation of the Federal Resource Conservation and Recovery Act is expected to result in a reduction in groundwater pollution, a reduction in hazardous waste dumping, and shifting of the cost of hazardous waste disposal from the taxpayer to the industry. The costs for disposal of hazardous wastes may increase, and there may be a shortage of available disposal sites. However, many hazardous industrial wastes are disposed on site, exempting them from close scrutiny. (Carroll-FRC)

A CASE STUDY OF RURAL OPPOSITION TOWARD RIVER VALLEY PLANNING,
W. Bolstad, B. Mathur, and H. MacKnight.
Canadian Water Resources Journal, Vol 6, No 4, p 141-156, 1981. 3 Fig, 4 Ref.

Descriptors: *Water management, *Public opinion, *Rural areas, *Meewasin Valley Authority, *Saskatchewan, Public relations, Public participation, Recreation, Social aspects, South Saskatchewan River, Saskatoon, Water policy, Water law, Water resource development, River basins, Canada.

The Meewasin Valley Authority, established in October 1979 to protect and develop the South Saskatchewan River Valley's resources for recreational and other purposes, met opposition from the rural constituency soon after its organization. Initial opposition was from realtors and others with interests in land. The River Edge Heritage Association became the nucleus of the dissenters, who gained considerable political power. Several mistakes fueled the controversy. Committee members were not well informed about the objectives of the Authority prior to the planning process. As work progressed some realized they did not agree with the objectives. Of the public interest groups invited to praticipate in planning, none represented the rural interests. This was not a purposeful omission, but planners did not know that rural areas are rarely represented by well-organized interest

groups. The conceptual plan had not been based on recreational demand studies and included in the natural system jurisdiction much land for which there were no plans. As a result of public opposition the Authority's Act was amended and some powers were removed and diluted. An appeal mechanism was also added. (Cassar-FRC)

A FEDERAL PERSPECTIVE ON RIVER BASIN MANAGEMENT,
Department of the Environment, Vancouver (British Columbia). Inland Waters Directorate (Pacific Region).
R. L. Pentland.
Canadian Water Resources Journal, Vol 6, No 4, p 80-94, 1981.

Descriptors: *Water management, *Federal jurisdiction, *Water policy, Planning, *Canada, Water resources development, Public participation, Data collections, Research priorities, Governmental interrelations, Local governments, Provincial jurisdiction, Jurisdiction, River basins.

The role of Canada's Federal government in water management has evolved from that of primary developer to one of joint shared responsibility with provincial or local governments. Since the passage of the Canada Water Act in 1970 and other legislation, the expensive, time-consuming comprehensive approach to planning has been changed to a more action-oriented, site-specific approach. Examples of recent evaluation processes illustrate the informal customized approach. Some studies use a formal structured procedure, and others use only those steps necessary to obtain the desired results. The philosophy of data collection is to use existing data and analytical tools maximally, because time and resources for new data and tools are not usually available. Public consultation is applied extensively at all stages of planning. Methods of obtaining and transmitting information are tailored to the type of population, type and extent of communication networks, and existing level of awareness on environmental issues. During the next decade the trend toward further federal concentration international and interprovincial systems is expected to continue. Emphasis will be placed on defining numerical values of water quality and quantity. Comprehensive planning will be undertaken only when necessary, with more attention to local issues. Other major concerns will be balancing water supply and demand, research in the field of demand management, streamflow regulation and apportionment in interjurisdictional situations, and integration of model development and data collection. (Cassar-FRC)

RIVER BASIN PLANNING IN ALBERTA, CURRENT STATUS--FUTURE ISSUES,
C. L. Primus.
Canadian Water Resources Journal, Vol 6, No 4, p 44-50, 1981.

Descriptors: *Planning, *Water management, Land use, River basins,*Alberta, Water resources development, Water transfer, Water allocation, Water quality, Economic development, *Legislation, Canada.

In Alberta water resources are managed on a river basin basis. The six major basins are Oldman, Bow, Red Deer, North Saskatchewan, Athabasca, and Peace. The basic objective of water resources management is to support the overall economic and social objectives of the province and to ensure that good quality water is not a limiting factor in achieving these objectives. Legislative acts dealing with water resources management are the Water Resources Act (concerns only the water resource), the Public Lands Act, and the 1977 Planning Act (land use planning and regulation). To date 7 basin and sub-basin plans have been completed and are being implemented. More comprehensive long range planning for the major basins has started with the South Saskatchewan River basin. Major issues in water management are allocation of water between basins, reallocation of existing supplies to more beneficial uses, water supply and quality as constraints to development, and establishing minimum flow requirements for stream maintenance and fisheries habitat protection. RIVER BASIN MANAGEMENT IN ONTARIO,
J. R. Powell.
Canadian Water Resources Journal, Vol 6, No 4, p 51-65, 1981. 1 Fig.

Descriptors: *Water management, *Political constraints, *Local governments, *Ontario, Canada, River basins, Conservation Authoriities, Institutional constraints, Governmental interrelations, Financing, Water policy, Water resources development.

River basin management in Ontario is carried out by 39 Conservation Autorities, corporate bodies established by order-in-Council at the request of two thirds of the participating municipalities. This implies local management of water resources with support of the provincial and federal governments. Although significant accomplishments have been made under this system, there are many shortcomings and problems, largely political, financial, or structural. Political impediments include unclear and irrelevant policies on water management objectives, the push to eliminate Conservation Authorities and other special-purpose bodies, and the fact that authority members are not directly elected. Financial impediments include conditional grants, the proliferation of government personnel in the paperwork and administration aspects of water management, and the use of money generated by natural resources (such as forests) for popular social programs rather than for reinvestment in the resources. Structural impediments are lack of authority and jurisdiction to carry out programs, the large number of river basins not included within a Conservation Authority, and fragmentation in the extension services and in the agencies which provide money to the Conservation Authorities. The most cost-effective way of handling water resource management is a major increase in local responsibility. Some ways of accomplishing this are direct election of Conservation Authority members, deconditionalizing of grants, charging users for services, a five-fold increase in budgets, development of comprehensive river basin plans, transfer of many of the resource management functions to the Conservation Authorities, and removal of political structures. (Cassar-FRC)

PROMISING STEPS TOWARD A NEW OTTAWA RIVER REGULATION,
A. Harvey.
Canadian Water Resources Journal, Vol 6, No 4, p 174-186, 1981. 2 Fig, 5 Ref.

Descriptors: *Flood control, *Reservoir operation, *Water management, *River basins, Flow regulation, Ottawa River, Montreal, *Quebec, Ottawa River Regulation Planning Committee, Planning, Reservoir storage, Optimization, *Water policy, Water resources development, Canada.

The Ottowa River Regulation Planning Committee was established in 1977 to recommend flood regulation measures for the 146,334 sq km basin, located in Quebec and Ontario. The river system was well developed, with 30 large reservoirs and many smaller ones, used for hydroelectric power generation, logging, recreation, flood control, and navigation. The Committee's final report, issued in December 1980, recommended an administrative structure and use of a flexible linear optimization model for integrated operation of the existing reservoir system. This integrated operation was expected to produce a 10% flow reduction, with expectation of further flow reduction with improvements in models and forecasting and construction of new reservoirs. (Cassar-FRC)

NEW STRATEGIES FOR WATER RESOURCE PLANNING IN BRITISH COLUMBIA,
Department of the Environment, Victoria (British Columbia).
J. O'Riordan.
Canadian Water Resources Journal, Vol 6, No 4, p 13-43, 1981. 6 Fig, 5 Tab.

Descriptors: *Water management, *Planning, *Watershed management, *British Columbia, Canada, *Water resources development, Regional planning, Water quality management, Fisheries, Okanagan River, Nicola River, Strategic planning, *Water policy, Water resources development, River basins.

British Columbia experiences a variety of problems in water quality and managment--sedimentation from forestry, lake eutrophication, pollution from industrial discharges, lake shore developments, reservoir level fluctuations, flooding, and hydropower, development in scenic rivers. Provincial response has usually been reactive, emphasizing allocation and regulation rather than long-term management. Some more comprehensive planning and implementation programs have been undertaken with less than satisfactory results. These shortcomings have led to a new approach, strategic planning, combining comprehensive planning with increased flexibility. This approach is characterized by a regional concept (one or more watersheds), integration of water and related issues, use of existing data, and commitment to implementation. The strategic planning system is two-tiered. A policy framework is provided for a set of operational activities on a more site-specific basis. This method is illustrated using improvement in water quality for streams in the Nicola Basin, balancing the irrigation interests against the fisheries interests. (Cassar-FRC)

THE STATUS OF GROUNDWATER LAW IN NEW YORK STATE,
S. J. Spiegel.
Clearwaters, Vol 11, No 4, p 15-16, 1981.

Descriptors: *Groundwater, *Legal aspects, *Water quality, *New York, Regulations, Legislation, Standards, *Groundwater management, Groundwater pollution.

Groundwater law in the urban, industrially oriented eastern United States has reflected the area's relatively abundant water supply. The policy of the common law has been to encourage consumption of water rather than to protect the resource from abuse. Regulations do not effectively address all aspects of the groundwater picture. Problems which have affected groundwater fall into four categories: direct wastewater discharge to the aquifer from septic tanks, etc.; land disposal of waste in landfills, where even relatively harmless solids can result in leachate contaminating surrounding waters; contamination by non-disposal activities such as petroleum exploration, mining, storage tank spills, irrigation return flow, and infiltrating stormwater; and the relationship between depletion and pollution, including instances where withdrawal modifies natural patterns of hydrologic flow. New York regulations which contain references to groundwater protection include the Groundwater Classifications, Quality Standards and Effluent Standards, which define groundwaters and provide quality standards for potable and consumptive uses; part of the State Sanitary Code, which defines the term source of water supply; the Solid Waste Management Facilities regulations, which also defines groundwater; the Freshwater Wetlands Act, which serves to protect wetland functions, including that of a recharge area for groundwater resources; and the State Environmental Quality Review Act. In most cases the groundwater management policy is only secondarily implemented through water quality, hazardous waste and general environmental regulations. This may not provide effective protection of the

groundwater resource, especially in light of modern technological knowledge. (Baker-FRC)

INSTITUTIONAL CHANGE - WATER QUALITY MANAGEMENT,
R. D. Hennigan.
Clearwaters, Vol 11, No 3, p 6-7, 9-12, September, 1981. 2 Tab.

Descriptors: *Water quality, *Water management, *Legal aspects, Water resources development, Legislation, Regulations, *New York, Watershed management, Local governments, Lake watersheds.

Findings from the Central New York Water Quality Management Project have been summarized. It was learned from the study that water quality management is complicated by numerous regulations which frustrate local leadership and initiative; that under New York State constitutional law it is impossible to form local multi-county agencies; that many of the counties of Central New York operate under the county law, forcing many water quality management issues to be evaluated on a short term and out of context of other county activities; that lake watersheds usually encompass many municapilities and often cross county boundaries; and that effective water quality management programming can be effected be developing a comprehensive monitoring system. It was recommended that thee state constitution be amended so that counties can form multi-county agencies at their discretion to carry out regional missions under local control and direction; that county law should be amended to explicitly allow the counties to form water quality management agencies; that counties be allowed to develop and adopt administrative codes; and that an institutional mechanism be created to allow residents and users of lake watersheds to implement local action programs to protect water quality. THE RECOMMENDATIONS OF THE UNITED NATIONS WATER CONFERENCE (MAR DEL PLATA, 1977) AND RELATED MEETINGS, ON NATIONAL WATER LAWS,
International Water Resources Association, Buenos Aires (Argentina).
C. J. Cano.
Journal of Hydrology, Vol 51, No 1-4, p 381-391, May, 1981. 29 Ref.

Descriptors: *Legal aspects, *Water management, *Federal jurisdiction, State jurisdiction, Regulations, Water law, Planning, International law, Conferences.

Lawyers must work together with hydrologists, hydraulic engineers, sociologists, economists, planners, and administrators if they are to develop water laws which provide workable legal solutions to water resource management problems. This paper, prepared by a lawyer, is designed to provide non-legal professionals with information on the state-of-the-art of legal water science in the world as of 1977. Recommendations with respect to national water legislation and administration prepared by the United Nations Water Conference (U.N.W.C.), held in Mar del Plata, Argentina in 1977, and other preparatory or related international conferences are reported. Recommendations developed by the Conference addressed water policy and law, problems in preparing national water legislation, the content of water legislation, water law and water administration, and problems related to inter-jurisdictionality. The recommendations addressed such specific subject matter as water ownership; water rights; water engineering works; use of water by agriculture, fisheries, and industries; pollution; environmental impact; taxation and economic incentives; floods and other emergencies; scenic rivers; and users' participation in planning and decision-making. Recommendations made by the u.N.W.C. with respect to training and research in the field of water law are also discussed briefly. (Carroll/Frc)

SERVICING GROWTH IN THE METROPOLITAN TORONTO REGION DURING THE EARLY YEARS OF THE ONTARIO WATER RESOURCES COMMISSION: 1956-1968,
R. Bordessa, and J. M. Cameron.
Canadian Water Resources Journal, Vol 5, No 1, p 1-29, 1980. 1 Fig, 14 Ref.

Descriptors: *Urban development, *Land use, *Political aspects, Wastewater treatment, Ontario Water Resources Commission, Metropolitan Toronto Planning Board, Toronto, Ontario, Decision making, Sewer systems, Planning, Water policy, Water management.

The impact of the Ontario Water Resources Commission (OWRC) on growth in the metropolitan Toronto region is examined from 1956, the year of its inception, to 1968, the year of its maximum influence and beginning of curtailment in power. The origins and mandate of the OWRC and the overlapping interests and jurisdiction with the Metropolitan Toronto Planning Board (MTPB) are discussed. Three case studies illustrate the details of planning for sewage provision in the fringe areas of the city. Markham Village's request for a wastewater treatment plant to serve 4000 persons showed the decreasing effectiveness of the MTPB in maintaining the principle that servicing agreements should be contingent on planning for land use. During the several years that this request was unresolved, OWRC increased in importance and finally convinced the officials to approve funds necessary for construction. The OWRC also dominated the decision to install a package treatment plant in Markham Township rather than connect with the metropolitan Toronto sewage system as proposed by the MTPB. The eventual outcome of this case was connection with the metropolitan sewage system and a reversal of the OWRC's position on upstream plants. The last vestiges of MTPB's control over growth in fringe areas were removed by the water and sewage services plan promoted by the OWRC in South Peel. This $80 million scheme services 200 sq miles and a projected 1 million people. Growth in the outlying areas of Toronto during this period was clearly a result of servicing decisions rather than planned land use decisions. (Cassar-FRC)
W82-05566

FEDERAL WATER POLLUTION REMEDIES: NON-STATUTORY REMEDIES ARE ELIMINATED,
L. T. Vance.
Land and Water Law Review, Vol 17, No 1, p 105-137, 1982. 205 Ref.

Descriptors: *Water law, *Judicial decisions, *Legal aspects, Legislation, Water pollution, Nuisance, Regulations, Common law, Liability, Remedies, Damage, Federal Water Pollution Control Act Amendments.

Three Federal water pollution remedies--the federal common law of nuisance, the Federal Water Pollution Control Act Amendment of 1972 (FWPCAA), and private remedies implied from the provisions of the FWPCCA--are examined. In several recent decisions the U.S. Supreme Court eliminated the implied rights of action to enforce the FWPCAA and federal common law nuisance actions which seek to enjoin approved conduct. The pertinent cases were Illinois v. City of Milwaukee (which preceded the FWPCAA of 1972 by a few months), City of Milwaukee v. Illinois and Michigan (1982), and Middlesex County Sewerage Authority v. National Sea Clammers Association (1982). However, the court's decisions have effectively protected dischargers from liability for damages caused by their pollution. The federal common law of nuisance, which could play a supplemental role in achieving the goals of the FWPCAA, should be preserved to encourage citizens and states to undertake litigation against polluters. (Cassar-FRC)

HISTORY, PRACTICE AND EMERGING PROBLEMS OF WETLANDS REGULATION: RECONSIDERING SECTION 404 OF THE CLEAN WATER ACT,
Popham, Haik, Schnobrich, Kaufman and Doty Ltd., Denver, CO.
G. E. Parish, and J. M. Morgan.
Land and Water Law Review, Vol 17, No 1, p 43-84, 1982. 138 Footnotes.

Descriptors: *Water law, *Wetlands, *Dredging, *Permits, Regulations, Clean Water Act, Fill permits, Water quality control, Legislation, Jurisdiction, Navigable waters, Legal aspects, Fish, Wildlife, Spoil disposal, Land use.

Section 404 of the Clean Water Act required potential dischargers to secure permits from the Corps of Engineers before dredge or fill materials are dumped into navigable waters. Securing a permit is very difficult, entailing complex application procedures and involvement with several federal agencies. This paper examines the Section's deviations from the Congressional purpose and constitutional foundations of water law, the process problems involved in securing a permit, and suggestions for facilitating the process. Jurisdictional problems arise in the definition of whether a wetland is water and which waters are considered navigable. Permits are not needed for dredged and fill material from several specified activities such as agriculture, structure maintenance, and construction of irrigation or drainage ditches and ponds. General permits, allowing some activities to take place without going through the application process, were intended to simplify the process but have produced the opposite result. Standards for permit review have been broken down into 12 general policies, the most important of which are public wildlife. Permit processing procedures are described for routine cases and cases in which controversy is expected. Suggestions for reform are discussed under the categories: legislative (jurisdictional, permit standards, permit procedures reform) and alternatives to wetland protection (regulatory and nonregulatory). CONFLICT BETWEEN ESTABLISHMENT OF INSTREAM FLOWS AND OTHER WATER USES ON WESTERN STREAMS,
Colorado State Univ., Fort Collins.
R. L. Anderson.
Water Resources Bulletin, Vol 18, No 1, p 61-65, February, 1982. 7 Ref.

Descriptors: *Instream flow, *Legal aspects, *Water rights, *Water use, Water management, *Competing use, Water allocation, Water supply, *Western United States.

Concentrated efforts have been made in the past two decades to establish and legitimize public use of water for recreation, scenic, esthetic, water quality, fisheries, and similar instream uses. However, application of minimum instream flow policies and programs to western rivers can result in conflicts with other long established users as a result of climatic conditions. The economic and social structure of many western areas is dependent on utilization of limited and highly stochastic water supplies. In some cases, the specified flow required to meet the instream flow uses exceeds the average natural flow of the particular river. In many other cases, the specified instream flow requirement would necessitate diverting flow from uses already in place or from anticipated and already-planned uses. Many of the current users have made significant financial investments in systems which depend on access to given water supplies. In addition, water rights in western states constitute property rights subject to due process and compensation. Therefore, attempts to deprive these users of their current water supplies could be expected to result in intense legal proceedings with respect to constitutional rights and property rights. It is concluded that establishment of minimum instream flows on western streams will be difficult and costly in many cases, create conflict in almost all instances, and disrupt established water uses or threaten to disrupt water development plans of many users. (Carroll-FRC)

THE OKANAGAN BASIN AGREEMENTS--AN EXAMPLE OF INTEGRATED WATER RESOURCE PLANNING IN BRITISH COLUMBIA,
A. M. Thomson.
Canadian Water Resources Journal, Vol 5, No 3, p 6-14, 1980. 2 Fig.

Descriptors: *Water management, *Water policy, Okanagan River, *British Columbia, Canada, Planning, Water quality, Water supply, Recreation, Fisheries, Environmental effects, Social impact, Flood plain management, Flow regulation, Public opinion.

The Okanagan Basin Study and subsequent Implementation Agreement illustrate integrated water resources planning in British Columbia. Two major problems exist in this arid, warm region, 3165 sq miles in area: extremely variable annual runoff (80,000 to 800,000 acre feet) and deterimorating water quality caused by population growth. The Basin Study, undertaken jointly by the provincial and federal governments in 1969-73, developed a framework plan for water management to the year 2020. Goals were not limited to economic growth as in the past, but also included environmental quality and social betterment. In February 1976 the provincial and state governments entered into an Implementation Agreement. The main activities involve development actions to achieve plan objectives, monitoring of the effectiveness of these actions, and a comprehensive review in 1980 and 1981. Major components of development action are water quantity, water quality, fisheries, and recreation. Public response will be reflected during the implementation phase. (Cassar-FRC)

AMERICAN INDIAN WATER RIGHTS AND THE USE OF COLORADO RIVER WATER,
S. K. Smith.
Water Supply and Management, Vol 6, No 1-2, p 75-86, 1982. 1 Fig, 4 Tab.

Descriptors: *Riparian rights, *Water law, *Colorado River, *River basin development, *Water demand, Water rights, River basins, Water resources development, Water policy, Legal aspects, Resources development, Water supply development, Natural resources.

Indian Water rights are considered paramount over nonIndian water rights because nearly all Indian reservations were created prior to the diversion of waters from the rivers of the Western United States by nonIndian interests. This theory was reinforced by the Supreme Court decision in the case of Winters vs. U. S., in which it was stated that Indians has command of the lands and the waters on Indian reservations. The quantification of these water rights is still being litigated for Indian reservations in the Colorado River Bbasin. The waters of the Colorado River are important to the Indians not only for domestic and agricultural needs, but for sacred purposes and fishing as well. Significant energy resources are located on Indian lands, but many impediments exist to their development. More compromise between factions of varying interests will be needed in the future for the development of competing water demands and the definition of Indian water rights. (Geiger-FRC)

FLOODS OF SEPTEMBER 16, 1975 IN TALLABOA VALLEY, PUERTO RICO,
Geological Survey, San Juan, PR. Water Resources Div.
K. G. Johnson.
Geological Water Resources Investigations, Open-File Report 80-1283, April 1981. 5 Sheets, 10 Fig, 1 Tab, 4 Ref.

Descriptors: *Floods, *Floods frequency, *Flood peak, *Flood plain management, Flood discharge, Flood recurrence interval, Flood profiles, Flood data, *Puerto Rico, *Tallaboa Valley.

The most severe flood since 1928 inundated the Rio Tallaboa Valley on the south coast of Puerto Rico on September 16, 1975. Peak discharge was about 666 cubic meters per second. The flood has an estimated recurrence interval of 20 years. The data provided in the report can be used in making rational decisions in formulating effective floodplain regulations that would minimize flood problems in the Tallaboa Valley. (USGS)

THE UNCERTAIN QUEST FOR A MANAGEMENT STRATEGY IN THE FRASER ESTUARY,
British Columbia Univ., Vancouver. Westwater Research Center.
A. H. J. Dorcey.
Canadian Water Resources Journal, Vol 6, No 4, p 95-118, 1981. 3 Fig, 1 Tab, 12 Ref.

Descriptors: *Water management, *Planning, *Decision making, Water quality management, *Fraser River, *Estuaries, River basins, Management, Data collections, Political constraints, Institutional constraints, Water policy, Water resources development, *British Columbia, Canada.

The growing pressure of conflicting interests in the Fraser River estuary led to intensive planning activities during the 1970's. The expansion of the Vancouver Airport was a catalyst in development of an estuary management plan. The Fraser River estuary study was initiated in 1977 to focus on all uses of estuarine resources. In Phase I reports were prepared on land use, transportation and port development, water quality, recreation, and habitats. This pointed out the need for a comprehensive management plan, designated as Phase II and scheduled for completion in 1982. Progress has been made in generating information necessary for decision making, especially from the required environmental impact assessments. Description knowledge is presently fair to very good in most fields, but functional knowledge (causes and effects) is still only poor to fair, except in hydrology. This lack of knowledge is a major constraint on decision making. Negotiations have been successful within the government but not among non-governmental interests. Phase I suggested new institutional arrangements for linking decision making with organizational arangements for planning. Three interagency groups were suggested: a constituency (all interested parties), a policy group (key agencies), and an estuary council (small group responsible for formalizing policies). ILLINOIS WETLANDS: THEIR VALUE AND MANAGEMENT,
Rock Valley Metropolitan Council, Rockford, IL.
H. E. Bell, III.
Illinois Institute of Natural Resources, Chicago, Document No 81/33, October 1981. 133 p 5 Fig, 12 Tab, 121 Ref.

Descriptors: *Wetlands, *Wildlife habitats, *Wildlife conservation, *Resources management, Ecol-

ogy, *Drainage, Sediments, Water pollution control, Permits, Economic justification, Swamps, Marshes, Soil types, Soil saturation, Preservation, *Illinois.

In the last 100 years, approximately 99.5 percent of Illinois wetlands has been destroyed because they were considered useless and the land could be put to better use with higher economic yield. This report details the diverse value of wetlands and outlines the means of preserving, restoring, and managing them. Wetlands are valuable for many reasons: they provide a habitat for threatened and endangered species; they filter pollutants from rivers and lakes without the high cost of treatment plants, i.e., excessive nutrients are chemically locked into wetland soil or absorbed by plants; and they can act like sponges during floods by storing water in floodplain forests, in depressions like shrub swamps and marshes, or in sandy soils. There are also potential benefits in treating wastewater with artificial wetlands. Most Illinois wetlands are theatened with destruction; federal, state, and local laws---404 permits, Section 10 permits, the Endangered Species Act---do not provide adequate protection. Local citizens need to take a more active role in wetlands protection and management by voicing their concerns to the agencies responsible for administering the regulations, such as regional planning commissions and councils of governments. Wetlands can be protected by public acquisition, such as by the U.S. Fish and Wildlife Service and the Illinois Department of Conservation. Landowners must also protect their wetlands from adjacent land use that can disturb their hydrology or vegetation. Wetlands are not wastelands and should be managed for all the benefits they offer. Preservation is the best type of management. (Atkins-Omniplan)

Descriptors: *Bottomland, *Swamps, *Ecology, *Hydrology, *Flood plains, Wetlands, Runoff, River systems, Fauna, Plant populations, Geochemistry, Water level fluctuations, Erosion, Soil water, Flooding, Hardwood swamps, Southeast United States.

Bottomland hardwood forests and their fauna comprise remarkably productive riverine communities adapted to a fluctuating water level ecosystem characterized and maintained by a natural hydrologic regime of alternating annual wet and dry periods. This community profile has been prepared in part to provide information for management decisions. The entire bottomland over which flooding occurs is a functional part of the wetland system and must be considered as a unit when making resource decisions. Water is the driving force of the bottomland hardwood community. Sources of water to bottomlands include precipitation and runoff from mountains and Piedmont, groundwater from rainfall, underground aquifers, continuous seepage from sand aquifers, and tidal flow. The physicochemical environment of the floodplains is a function of the interactions or processes occurring in the water column, in soil, and at the soil-water interface. The plant species and communities that inhabit the floodplain can be considered as buffers that absorb and dissipate the physical energies of the riverine system. Water movement is slowed and erosion is held in check through the anchoring of sediments by root systems, the deposition of sediments that are dropped from the slowed water column, and the reduction of the water column by the spreading out of water. The buffering role of the plant communities is also evident in the biogeochemical cycles of the riverine-palustrine system. The moisture gradient and hydroperiods of floodplains provide a continuum for a diverse fauna. Bottomland swamps are integrally coupled to the surrounding uplands, downstream estuarine systems, and the atmosphere. (Moore-SRC)

Descriptors: *Geothermal resources, *Environmental effects, *Social impact, *Economic impact, *Geothermal power, Resources development, Public health, Subsidences, Cooling water, Injection, Irrigation, Wastewater disposal, Irrigation-return flow, Salinity, Salton Sea, *Imperial Valley, California.

The Imperial Valley contains nearly a third of the nation's identified hot-water geothermal resources. The valley, with its 475,000 acres of irrigated lands and warm climate, also represents one of the more important agricultural resources of the United States. The most important potential impacts involve air quality changes resulting from emissions of hydrogen sulfide, and increases in the salinity of the Salton Sea resulting from the use of agricultural waste waters for power plant cooling. Extensive withdrawals of agricultural waste waters to support geothermal development will accelerate increases in the Salton Sea's salinity, putting added stress on its quasi-marine ecosystem. Large withdrawals of waste waters would not be necessary if steam condensate was used as the sole source of cooling water for flashed-steam power plants. A county policy favors the full injection of withdrawn geothermal fluids in order to protect against land subsidence, and therefore external sources of water will probably be needed for geothermal operations. For the most part, geothermal activities will be compatible with irrigated agriculture, but negative impacts of a site-specific nature caused by land subsidence, cooling tower drift, or accidental spills of geothermal fluids could occur. Residual geothermal fluids will be disposed of by subsurface injection to geothermal reservoirs. The socioeconomic consequences of geothermal development will generally be beneficial. (Moore-SRC)

The ecological results of the proposed Danube-Dnieper water diversion project must be considered in the planning stage. The project involves water bodies of different types: rivers, estuarine regions, salt water lagoons, canals, and conduits. Many changes in water quality and biological life will be produced by water resources development in this region. Closing the estaries will freshen water there, replacing marine ecosystems with fresh water ecosystems. Limitation of discharge into the Black Sea will change the salinity and the nature of the aquatic life there. Construction of the Ochakov barrage will transform the Dnieper-Bug salt lagoon into a fresh water body and act as an obstacle to diadromous fish spawning. However, reproduction of bream, pike, and perch will be improved. The nature of the artifical water courses (canals and closed conduits) and pumping stations can profoundly affect water quality and phytoplankton populations. Possible effects on the land include changes in groundwater levels, salinization, and vegetation changes. (Cassar-FRC)

ENVIRONMENTAL ASPECTS OF MULTIPURPOSE RESERVOIR PROJECTS IN DEVELOPING COUNTRIES,
H. F. Ludwig.
Water Science and Technology, Vol 14, No 1/2, p 269-280, 1982. 1 Fig, 1 Tab, 12 Ref.

Descriptors: *Environmental impact statement, *Developing countries, *Water resources development, *Thailand, *Multipurpose reservoirs, Planning, Reservoirs, Dam effects, Mekong River, Fisheries, Forestry, Wildlife, Economic impact, Social impact, Monitoring.

In Thailand water development projects have been planned to meet specific needs (power generation, irrigation, and flood control), with little attention paid to environmental impacts. This traditional attitude needs to be modified to consider effects of reservoirs on water quality and ecology to make them truly multipurpose. Fisheries, forestry, wildlife, agro- and other local industries, families in the zone of inundation, and villages outside the flooded region are all environmental issues which should be included in total planning. Continued monitoring of project impacts after construction, rarely done at present, can be valuable in planning future projects. Supplemental tables and graphs give suggested budget allowances for environmental impact assessment studies in Thailand and environmental impact guidelines for dams and reser-

voirs. For additional help 25 references on environmental impact statement methodologies which are applicable to dam and reservoir projects and six environmental impact statement reports on Thailand projects are given in the appendix. (Cassar-FRC)

THE LONG LAKE DIVERSION: AN ENVIRONMENTAL EVALUATION,
Ontario Ministry of Natural Resources, Thunder Bay.
S. E. Peet, and J. C. Day.
Canadian Water Resources Journal, Vol 5, No 3, p 34-48, 1980. 3 Fig, 15 Ref.

Descriptors: *Environmental effects, *Diversion structures, *Water transfer, Long Lake, Ontario, Lake Superior, Aguasabon River, Kenogami River, Albany River, Interbasin transfers, Social impact, Economic impact, Logging, Pulp and paper industry, Reservoirs, Canals, Rivers, Water management, Water quality, Water pollution effects, Recreation, Aesthetics, Erosion, Shores, Aquatic life, Fish, Hydroelectric stations, Dams.

The environmental effects of the Long Lake Diversion, northern Ontario, were evaluated. The first phase, consisting of two dams and a 5-1/4 mile diversion canal, redirected the northward flowing Kenogami River south to Lake Superior. The second phase, completed in 1948, added a dam and hydroelectric station. At that time power generation and interbasin pulpwood transportation began. Effects of the four types of hydrologic modifications were: (1) downstream--highly variable flow conditions, habitat losses, decreased biological production, esthetic impairment, little socioeconomic effect, (2) Long Lake receiving water body--alteration of 10 miles of the Kenogami River with resultant navigational and esthetic impairment, severe shoreline erosion, flooding, accumulation of logging debris, interference with a municipal water supply inlet, damage to an Indian cemetary, (3) diversion channel--disturbance of fish habitats and interbasin movement, temporary construction effects, increase in aquatic macroinvertebrates, damage to fish spawning beds, impairment of water quality and esthetic values, and (4) reservoir--minimal effects due to good planning. Forty years of log handling has negatively affected water quality, aquatic communities, and recreational users. However, economic analysis and a public opinion questionnaire indicated that the overall social and economic benefits have exceeded the negative effects. (Cassar-FRC)

Water Resources Bulletin, Vol 18, No 2, p 297-305, April, 1982. 4 Fig, 1 Tab, 26 Ref.

Descriptors: *Diversion structures, *Environmental effects, *Reservoirs, *Canada, Long Lake Diversion, Ogoki Diversion, Ontario, Great Lakes, Social impact, Economic impact, Aquatic habitats, Recreation, Fish, Logging, Erosion, Silting, Hydroelectric power, Water transfer, Interbasin transfer, Turbidity, Benefits, River basins.

Biophysical and socioeconomic effects of the Ogoki Diversion and the Long Lake Diversion, two small basin water diversion projects in Ontario, are described. Both projects have produced valuable benefits--hydroelectric power, log transport, access roads, and economic development. Problems have been caused by failure to clear trees before inundation, water level fluctuations, erosion, siltation, reduced or increased river flows, and debris from log transport. As a result of the perturbations, aquatic communities have been eliminated or changed; recreation and commercial fishing have been adversely affected in some sections; 11 acres of property on an Indian Reserve partly occupied and partly of archeological interest, have been lost through erosion; wild river reaches have been drowned; water quality has been impaired by pulpwood leachates; and the shoreline appearance has been impaired. It is suggested that early public participation is desireable in planning projects of this type and scale. The esthetic and other environmental disturbances should be avoided. River regulation in the north should be confined to certain watersheds, while allowing other basins to remain unchanged. (Cassar-FRC)

A CITIZEN'S VIEW OF WATER MANAGEMENT IN THE OKANAGAN VALLEY,
J. Woodworth.
Canadian Water Resources Journal, Vol 5, No 3, p 15-25, 1980. 1 Fig.

Descriptors: *Water management, *Water policy, *Clearcutting, History, Okanagan River, British Columbia, Planning, Population dynamics, Water supply, Forest management, Public opinion, Irrigation, Recreation, Fish.

The desert-like Okanagan Valley, British Columbia, did not support a sizeable population until irrigation began in the early 1900's. Subsequent water resources development after World War I stimulated population growth so that at present the area is a suburb of neighboring Vancouver, Calgary, and Edmonton. Land use conflicts have developed among residents desiring to water lawns and gardens, farmers, loggers, cattlemen, skiers, and fisherman. In particular, clearcutting and insufficient reforestation in the uplands watershed is widespread but out of view of most of the residents in the valley. Although a Basin Study and Implementation Agreement has provided for water management, the Citizens Task Force review of 1980 agreed on 2 priorities: central, rather than fragmented, water management and serious examination of the effects of clearcutting in the mountains. HYDROLOGIC MONITORING IN THE COAL FIELDS OF CENTRAL UTAH, AUGUST 1978-SEPTEMBER 1979,
Geological Survey, Salt Lake City, UT. Water Resources Div.
G. C. Lines, and G. G. Plantz.
Geological Survey Open-File Report 81-138 (WRI), 1981, 56 p, 30 Fig, 1 Plate, 13 Tab, 17 Ref.

Descriptors: Surface water, *Monitoring, *Water quality, *Networks, Data collections, *Coal mines, Hydrologic cycle, Streamflow, Flow characteristics, Flow measurement, Sediments, Mine drainage, Groundwater storage, Groundwater movement, Chemical analysis, *Utah, Wasatch Plateau coal field, Book Cliffs coal field, Emery coal field.

Surface-water quantity and quality were monitored at 12 gaging stations down-stream from mine and lease areas in the Wasatch Plateau, Book Cliffs, and Emery coal fields in central Utah. Measurements of base flow were made at 52 other sites in the region. The report describes the hydrologic setting of this important coal region and summarizes the surface-water data collected at the monitoring sites from August 1978 through September 1979. Coal mining and lease activities in each of the monitored basins also are described. Where possible, hydrologic impacts of coal mining are evaluated. Impacts include increases in streamflow and degradation of surface-water quality due to water discharged from underground mines. Other impacts include removal of water from groundwater storage, changes in the natural ground-water flow system and possibly the diminution of spring flows. Adequacy of the monitoring network to detect hydrologic changes due to mining is evaluated. In order to fully assess and quantify the impacts, comprehensive studies and monitoring of the ground-water system and water produced in mines are needed. (USGS)

A RIVER CODING SYSTEM FOR WATER QUALITY ARCHIVES,
Fourth River Purification Board, Edinburgh (Scotland).
R. J. Sargent.
Water Pollution Control, Vol 80, No 5, p 682-686, 1981. 3 Fig, 1 Tab.

Descriptors: *Computers, *Coding systems, *River systems, Sites, Sampling, Gaging stations, Data collection, Data processing, Hydrologic data, Network design, Catchment basins, Great Britain.

The Forth River Purification Board in Edinburgh, Great Britain, has adopted a river coding system to describe the location of such features as sampling points, discharges, and gauging stations. The coding system was designed to facilitate the retrieval of information stored in various files on the computer, with respect to both available data relative to a given point and data relating to the position of a given geographical location within the river network. The constraints on the coding system were that the code should uniquely define a point on any and every watercourse, that the code should be as compact as possible, that the system should be sufficiently flexible to enable new watercourses to be added and varying densities of points to be identified, and that the system should have built into it the logic of the watercourse to enable accessing of upstream and downstream information from any given reference point. Each code has three parts: a number identifying the river catchment; a river number; and a distance number which gives the distance in river kilometers of the location from a defined starting point. Treatment of specific aspects of the hydrologic system and implementation on the coding system are described. (Carroll-FRC)

NEW DEVELOPMENTS IN AUTOMATED BIOSENSING FROM REMOTE WATER QUALITY STATIONS AND SATELLITE DATA RETRIEVAL FOR RESOURCES MANAGEMENT,

Tennessee Technological Univ., Cookeville.
E. L. Morgan, K. W. Eagleson, R. Hermann, and N. D. McCollough.
Journal of Hydrology, Vol 51, No 104, p 339-345, May, 1981. 2 Fig, 6 Ref.

Descriptors: *Sensors, *Remote sensing, *Bioindicators, *Water quality management, *Satellite technology, Fish, Fish behavior, Pollution load.

Increasing demands on water resources have intensified the need to maintain the environmental integrity of multipurpose drainage systems. As a result, there is increased interest in new, real-time methods for evaluating biological and physical-chemical water quality. A real-time automated biosensing unit has been designed which uses fish breathing rates as a measure of biological response or integration to water quality changes. Previous studies have shown that fish alter their typical breathing patterns in response to stressful conditions and that this function is a good physiological measure of chronic levels of a broad spectrum of toxic substances and environmental stresses. Biosensing units utilizing microprocessor-based monitors to measure fish breathing are interfaced to a remote data collection platform for satellite retrieval and transmission of data. The biosensor is used in conjunction with complex remote in-stream systems which collect information on a variety of physical parameters. These monitors, whiich are linked by radiotelemetry to central processing centers, may operate from such devices as buoys, mobile trailers, or stream-side stations. Real-time biological and physical data are transmitted to the data processing center, where they are readily available for interpretation by resource managers. (Carroll-FRC)

TOWARDS DIGITAL TECHNOLOGY IN THE MEASUREMENT AND CONTROL OF WATER LEVELS,
Churchill Controls Ltd., Reading (England).
J. W. Churchill.
Water Services, Vol 85, No 1030, p 599-600, 605, December, 1981. 5 Fig.

Descriptors: *Telemetry, *Remote sensing, *Water levels, Electronic equipment, Capacitance, Sensors, Transducers, Water depth, Automation, Computers, *Reservoirs.

The adoption of large digital telemetry systems by the service industries, including the water industry, is influencing the choice and development of the basic sensors and the forms of signalling they employ. The principle of capacitance for measuring liquid depth via immersion of a rod or wire is not new, but successful application of this principle was difficult. In a new device a concentric construction was adopted with a grounded tube surrounding a sensitive capacitance electrode, combined with a new form of electronic sensor. The water rises inside the tube to the same level as its surroundings and changes the capacitance of the wire in a manner strictly proportional to the water depth. The change in capacitance is substantial -- on the order of 2500 pf per meter. The polarity reversal time of the capacitor forms a type of audio frequency oscillator, whose signals can be transmitted over an ordinary telephone line or radio link. The transducer calibration is not voltage dependent; batteries or line voltage may be employed. The receiving circuit in its simplest form comprises an analog converter, which may give a reading on a meter or actuate high and low level signals. For digital use, microprocessor chips receive the signal as a pulse count which is timed against the processor's crystal clock. Thus a direct measure of water depth is obtained which is entirely independent of analog voltage references and is suitable for intermittent interrogation. (Carroll-FRC)

CONTINUOUS MEASUREMENTS OF DISSOLVED OXYGEN IN WATER CULTURE BY A SELF-CALIBRATING MONITOR,
Ben-Gurion Univ. of the Negev, Beersheba (Isreal). Dept. of Electrical Engineering.
S. Ben-Yaakov, and Y. Ben-Asher.
Water Research, Vol 16, No 2, p 169-172, February, 1982. 5 Fig, 7 Ref.

Descriptors: *Dissolved oxygen, *Measuring instruments, Monitoring, Eutrophication, Water quality, Calibrations, Technology, *Analytical techniques.

A study was conducted to develop a self calibrating oxygen monitor for continuous measurements in water culture. The self-calibrating oxygen system (SCOS) developed is described. The probe is suitable for installation and in situ monitoring of oxygen concentration in hydroponics installations and other water bodies. The sensor comprises a gold cathode, a silver anode and a teflon membrane separating the internal electrolyte from the test solution. The current output of the sensor is fed to a temperature compensating current-to-voltage converter which is built around a commercial operational amplifier with a thermistor in the feedback loop. The thermistor was chosen to provide temperature independent reading of the partial pressure of oxygen. The sensor was mounted in a flow-through cell through which the solution was circulated by a submerged centrifugal pump. The flow-through cell design was such that it will empty when the circulation pump is stopped. This feature is applied during the autocalibration phase, in which air is used as a partial pressure oxygen standard. Specially designed self-adjusting electronic circuitry is activated during the autocalibration stage to adjust the overall gain of the instrument so that the output reading will reach the desired leve. The gain is then left constant until the next autocalibration cycle. The temperature dependence of the uncompensated sensor response followed the theoretical relationship. The present configuration of the flow cell permitted rapid and simple maintenance of the dissolved oxygen sensor. The maintenance routine requires cleaning of the sensor's head by fresh water once a month and replacement of membrane and internal solution every 3 months. When monitoring highly eutrophic solutions a more intensive maintenance schedule is needed. (Baker-FRC)

DEVICE FOR CONTINUOUS MEASUREMENT OF PRIMARY PRODUCTION OF WATER BODIES AND BIOCHEMICAL OXYGEN DEMAND,
Moscow State Univ. (USSR).
G. G. Shinkar, V. V. Sapozhnikov, and A. A. Georgiev.
Water Resources, Vol 8, No 2, p 205-209, March-April, 1981. 3 Fig, 1 Ref. Translated from Vodnye Resursy, No 2, p 156-160, March-April, 1981.

Descriptors: *Primary productivity, *Dissolved oxygen, Productivity, Algae, Oxygen, *Biochemical oxygen demand, Lakes, Measuring instruments, Technology.

A productiometer was developed to measure primary productivity from the difference of oxygen concentrations in light and dark bottles. The bottles are installed in the water body at 0.5 m depth. Water is pumped through both bottles at the same rate. Dissolved oxygen is measured in both light and dark bottles, and the difference is used to calculate the gross productivity of the phytoplankton. These measurements are read by remote detectors and recorded automatically on shore. Glass cylinders are more satisfactory than rectangular glass boxes. This continuous method gives higher results than the traditional optimal conditions for light and nutrient supply. (Cassar-FRC)

PROCEDURES FOR THE COLLECTION OF REPRESENTATIVE WATER QUALITY DATA FROM MONITORING WELLS,
Illinois State Water Survey Div., Campaign; and Illinois State Geological Survey Div., Champaign.
J. P. Gibb, R. M. Schuller, and R. A. Griffin.
Cooperative Groundwater Report 7, 1981. 22 Fig, 10 Tab, 27 Ref.

Descriptors: *Water sampling, *Water analysis, Monitoring, Well data, *Water quality, Sample preservation, Chemical properties, On-site tests, Water quality standards, Drawdown, Operating policies, Pumping tests, Submersible pumps, Well filters, *Waste dumps, *Leachates, *Illinois.

Regulatory agencies are charged with setting design and operational standards for waste disposal facilities to insure that the environment is not adversely affected. Well sampling is the usual method of monitoring the effects on goundwater. The purposes of this study were to determine: (1) if current sampling methods yield representative samples of the aquifer being monitored; (2) if field samples must be treated (filtered and acidified) on-site of if they can be taken to a lab for treatment and suffer no chemical alteration; and (3) which sampling and preservation methods should be accepted as standards for monitoring well sampling. Four types of pumping methods were used to collect samples from monitoring wells at six Illinois sites. The selection of the type of sampling device; sample preparation, preservation, and storage; and sampling procedures all must be tailored to the size and accessibility of the individual well, its hydrologic and chemical character, the chemical constituents of interest, the time of year, and the purpose for monitoring. Generally recommended sampling procedures include: (1) using peristalsis or submersible diaphragm type pumps; (2) conducting pump tests prior to sampling to determine sampling frequency and time and rate of pumping; (3) flushing the well by pumping 4-to-6 well volumes; (4) measuring pH, specific conductance, oxidation-reduction potential, and alkalinity at the time of sample collection; and (5) filtering samples immediately on-site through a 0.45 millimicron pore size filter and then preserving the samples immediately after filtration, according to U.S. EPA recommended procedures. A LOW-COST MULTICHANNEL RECORDING PIEZOMETER SYSTEM FOR WETLAND RESEARCH,
Massachusetts Inst. of Tech., Cambridge. Dept. of Civil Engineering.
H. F. Hemond.
Water Resources Research, Vol 18, No 1, p 182-186, February, 1982. 5 Fig, 6 Ref.

Descriptors: *Piezometry, *Wetlands, *Automation, Marshes, Water table fluctuations, Measuring instruments, Tidal marshes, Sonar, Piezometers, Costs.

An acoustic system for continuous recording of piezometric head in wetlands is composed of a sonar transmitter-receiver, consisting of a pulse generator, receiver, timer, display, and switching unit; a digital data logger; transducers and their cables, built from ordinary earphones; a power supply (12-volt lead-acid motorcycle battery); and piezometers for saltwater use. Costs vary from $500 for manual operation to $1000 for automatic operation, not including the cost of the data logger and data cassette ($1000 each). This system has a rapid response, avoids disturbances in piezometric head caused by human weight on the compressible peat surfaces, and permits automatic readings at short time intervals, during storms, and for long periods. ON THE DETERMINATION OF THE DEGREE OF WEEDAGE IN FLOWING WATERS (ZUR

ANSPRACHE DES 'VERKRAUTUNGSZUSTANDES' IN FLIESS-GEWASSERN),
E. Niemann.
Acta Hydrochimica et Hydrobiologica, Vol 8, No 1, p 47-57, 1980. 8 Fig, 2 Tab, 3 Ref. (No English summary).

Descriptors: *Data acquistion, *Aquatic plants, *Shoreline cover, Streams, Streamflow, Hydraulic properties, *Running waters, Bioindicators, Biological communities, *Numerical analysis, Seasonal distribution.

Weedage is defined as the development of the entire submerse and emerse phytobenthos within the summer median water level of flowing waters. The description of the weedage in order to draw conclusions regarding water treatment or evaluation necessitates consideration of both quantitative development and species composition. A simple, rapid procedure for obtaining this description was developed, comprising a ten-point scale derived from ecologic, developmental, hydraulic, and taxonomic considerations. A numerical rating, a descriptor category, and more detailed characterization are presented in a table. Detailed botanical knowledge is not required to utilize this classification scale. In addition, the vertical growth is quantified on a five-point scale and the horizontal growth (percent coverage of the water surface) on a nine-point scale. Tests of application revealed that this system required only a few minutes per application site, gave fairly constant evaluations for similar vegetation patterns on different water bodies, and permitted recognition of variation due to hydromorphological character, local changes in ecological factors, and seasonal patterns. Mapping using this system is also possible. Comparison with dry weight determinations at the same three recording points on three different dates showed that neither of these two procedures is ideal for all situations. However, the simplicity of the rating method means that larger numbers of assessments can be performed and the effects of random fluctuations minimized. (Carroll-FRC)

A PORTABLE SYSTEM FOR MEASURING WATER TEMPERATURE, CONDUCTIVITY, DISSOLVED OXYGEN, LIGHT ATTENUATION AND DEPTH OF SAMPLING,
Nature Conservancy, Grange-over-Sands (England). Merlewood Research Station.
D. G. Benham, and D. G. George.
Freshwater Biology, Vol 11, No 5, p 459-471, 1981. 10 Fig, 1 Tab, 8 Ref.

Descriptors: *Measuring instruments, *Temperature, Monitoring, *Water quality, *Specific conductivity, Dissolved oxygen, Sample preparation, Sampling, Water sampling, Water analysis.

A description is offered of equipment designed to overcome the inconvenience of handling several specialized instruments for monitoring water temperature by incorporating all the sensing circuits into one self-contained unit. The system is powered by a rechargeable battery pack and provides instantaneous digital readings of temperature, conductivity, dissolved oxygen, light attenuation and depth of operation. Most of the measuring circuitry is of a novel design and incorporated selected, temperature-tested components to improve sensitivity and increase stability. The instrument can also provide continuous time-records of each variable, or X-Y plots of selected variables against depth, when connected to suitable chart recorders. The prototype instrument was tested extensively in the field over a three year period and has proved reliable in a wide range of applications, Results are presented to demonstrate the use of the temperature and depth transducers in X-Y mode, the use os the temperature/conductivity probe in flow-through mode, improvement in response time gained by fitting a water circulator to the oxygen electrode, and the use of the light-ratio meter as a crude transmisso-meter. SIMPLIFYING NEUTRON MOISTURE METER CALIBRATION,
Science and Education Administration, Phoenix, AZ. Water Conservation Lab.
F. S. Nakayama, and R. J. Reginato.
Soil Science, Vol 133, No 1, p 48-52, January, 1982. 2 Fig, 3 Tab, 5 Ref.

Descriptors: *Moisture meters, *Calibrations, *Soil moisture meters, Nuclear moisture meters, Measuring instruments, Absorption.

A method is described for relating measurements of different neutron moisture meters with each other and using the relationships developed for calibrating other meters. The four neutron moisture meters used include a source strength mCi model, probe model, absorber-shield type, and scaler model. Soil moisture probes can be calibrated in the field by comparing them directly with a master reference probe, using the appropriate type of access tubing and covering a range of water contents. Plastic absorbers can be used as secondary standards and also for checking the performance of the individual probes. A whole series of interrelations between plastic absorbers and different soil types may be developed, to which the manufacturer or user could refer in obtaining a calibration curve suitable for the field site. Of the four methods compared, the simplest was found to be that of calibrating one master probe and comparing other probes with this under field conditions which were similar over a range of soil water contents. From the slope and intercept values which can be obtained, a reference regression equation can be developed that can be used to calibrate other probes in the laboratory. (Baker-FRC)

HANDLING AND MEASUREMENT TECHNIQUES FOR ANOXIC INTERSTITIAL WATERS,
Freshwater Biological Association, Windermere (England).
W. Davison, C. Woof, and D. R. Turner.
Nature (London), Vol 295, No 5850, p 582-583, February 18, 1982. 2 Fig, 23 Ref.

Descriptors: *Interstitial waters, *Measuring instruments, Chemical analysis, Water analysis, Polarography, *Iron, *Magnanese, *Sulfides.

A new method is presented for measuring Fe(II), MN(II) and sulfide ions in the interstitial waters of anoxic sediments which have been sampled using a simple corer. Rapid filtration directly into a polarographic vessel permits the extraction of interstitial water and the measurement of all three components, less than 5 minutes after subsampling the sediment. The non-destructive polarographic measurement is able to assess the extent of contamination by oxygen and to study subsequent reactions in the interstitial water. Because polarography is a nondestructive technique, any change may be continuously monitored on the same sample. Polarograms were made of the overlying lake water of Esthwaite Water, interstitial water of Esthwaite Water and interstitial water of Rostherne Mere. The interstitial water samples were taken from a sediment depth of 3-4 cm. The results for the overlying water were in good agreement with earlier studies. The interstitial waters seemed to exhibit a reduced solubility and, because the solid phase had more opportunity to age in the sediment than in the anoxic waters of the lake, support is given to the supposition that the aging solid phase controls the interstitial water concentrations. The method should be applicable to organic rich marine sediments. Because anodic stripping voltammetry uses the same equipment, this simple procedure could be used to measure trace metals in interstitial water. (Baker-FRC)

MICROCOMPUTER WATER QUALITY SIMULATION MODEL,
Camp, Dresser and McKee, Inc., Waltham, MA.
R. J. Hughto, and R. P. Schreiber.
Civil Engineering (New York), Vol 53, No 3, p 58-59, March, 1982. 2 Fig.

Descriptors: *Water quality, *Rivers, *Computers, Model studies, Mathematical models, Simulation analysis, *Fate of pollutants, Biological oxygen demand, Dissolved oxygen, Aberjona River, Massachusetts.

A water quality model computes concentrations of dissolved oxygen, BOD, and nitrogenous oxygen demand in a river or stream. Assumptions are: the river is divided into a series of reaches with uniform characteristics, steady-state conditions prevail, concentrations of dissolved oxygen, etc., and inflow rates are known at the upstream boundary and at all inflow points, longitudinal dispersion is negligible, and all variations occur in one dimension. The model program is listed with a sample run for a three-reach system. The program is interactive, prompting the user to input the parameters for each reach. The system was tested on the Aberjona River basin, Boston, Massachusetts, to obtain a preliminary analysis of the effect of existing pollutant sources on water quality and to predict the results of abatement measures. A RELIABLE DISSOLVED OXYGEN PROBE FOR WASTE WATER TREATMENT PLANTS,
J. M. Hale.
Water and Waste Treatment, Vol 25, No 1, p 35-36, January, 1982. 3 Fig.

Descriptors: *Measuring instruments, *Wastewater analysis, *Dissolved oxygen, Oxygen, Monitoring, *Wastewater treatment, Orbisphere Laboratories, Control systems, Aeration, Sensors.

An oxygen detecting system was developed for use under the harsh conditions encountered in a wastewater treatment plant aeration basin. Orbisphere Laboratories' Model 2716 overcomes some of the problems normally encountered in dissolved oxygen sensors. The features include: (1) low flow requirements (1 cm per sec produces 95% of the high-flow limit and 29 cm per sec, 99%), (2) no interference from entangled fibrous material, (3) strong teflon membrane, cleanable with a toothbrush, (4) very tight stable seal between membrane and sensor body, (5) insensitivity to hydrogen sulfide, and (6) solid state digital electronic construction. In a 60-day test in a wastewater plant aeration basin no maintenance of the probe was necessary. Differences between the Model 2716 results and those from a test probe were always less than the 0.23 ppm error inherent in the test probe. (Cassar-FRC)

Descriptors: *Remote sensing, *Satellite technology, *Water quality, *Automation, *Data transmission, Sensors, Telemetry, Monitoring, Toxicity, Mortality, Respiration, Detection times, Computers, Buoys, Data collections, Bioindicators, Streams, Rivers, Water pollution, Stream pollution.

Applications of remote water quality platforms at key locations in selected drainages are becoming increasingly important for water quality assessment. Testing was made of remote site-specific biosensing units for real-time water quality monitoring from cold water streams in the Great Smoky Mountains National Park to a warm water site on the Tennessee Cumberland River. The designed sensors monitored fish respiratory responses. The sensors were interfaced to existing water quality monitoring stations equipped with remote microprocessor-controlled data collection platforms. Biological responses and physical parameters were transmitted from the stations to over-passing earth satellites which retransmitted the data to a central data collection and processing center. These applications provided verification that real-time biological responses can be remotely monitored and simultaneously retrieved with physical water quality information via radiotelemetry systems. Laboratory prototypes of an automated toxicity assay monitor and a buoy system were also studied for remote biosensing applications. The toxicity monitor was tested and verified in a series of time-rated mortality studies, and the buoy configuration was found to be effective. (Zielinski-MAXIMA)

A FIELD TECHNIQUE TO DIRECTLY MEASURE RIVER BANK EROSION,
Alberta Research Council, Edmonton.
H. R. Hudson.
Environment, Vol 24, No 3, p 381-383, April, 1982. 1 Fig, 14 Ref.

Descriptors: *Rivers, *Erosion, Mathematical studies, *Measuring instruments, *Bank erosion, Monitoring, Sediment transport.

A new method is presented for evaluating the mode and spatial and temporal aspects of bank erosion. The method calls for sequential bank profiling from a fixed baseline using a stadia rod for vertical control and another stadia rod, Brunton compass, and meter rule for horizontal control. The method yields a rapid, accurate representation of river bank changes, using inexpensive, readily available equipment. When repeat surveys are performed at a relatively close spatial interval, which depends on the complexity of the bank, a three dimensional map of the bank may be drawn and volumetric changes may be calculated. These surveys should be supported by a photographic record of the profile sites. The time required to produce a single profile for a complex bank of 2 meters in height is about 5 minutes. Repeat surveys show that the precision of the technique is within 5 cm for a complex bank and difficult conditions. The accuracy and precision of measurement improve with less complex banks. The major limitations are access to the base of the bank and up the bank and ability to define sufficient relevant points in the cross section to accurately describe the bank. It is suggested that the technique may provide details of bank erosion of intermediate magnitude over periods of days to years. (Baker-FRC)

HUMIDITY MEASUREMENT BY INFRARED THERMOMETRY,
Science and Education Administration, Phoenix, AZ. Water Conservation Lab.
S. B. Idso.
Remote Sensing of Environment, Vol 12, No 1, p 87-91, 1982. 2 Fig, 12 Ref.

Descriptors: *Vapor pressure, *Air temperature, *Humidity, Temperature, Water vapor, Infrared Thermometry, Thermometers, Water stress, Remote sensing, Measuring instruments.

Humidity measurements necessary for remote sensing of plant water stress were performed with a new technique. The same infrared thermometer used to measure foliage temperature was used to obtain the vapor pressure measurement by viewing the cloudless sky directly overhead. Both the brightness temperature at 10.5-12.5 microns and the air temperature readings were obtained simultaneously and the values inserted into equations to calculate vapor pressure. A graph of calculted vs. measured vapor pressure obtained over a year's work showed deviations from the 1:1 line of + or - 3 mb for all but the lowest vapor pressures, which showed deviations of + or - 6 mb. The deviations were most prevalent in hot dry summer conditions and cool dry winter conditions. The method can be used in partly cloudy weather if the zenith is clear. (Cassar-FRC)

A LAND RESOURCE INFORMATION SYSTEM (LRIS) FOR WATER QUALITY MANAGEMENT IN THE LAKE ERIE BASIN,
Corps of Engineers, Buffalo, NY.
J. R. Adams, T. J. Logan, T. H. Cahill, D. R. Urban, and S. M. Yaksich.
Journal of Soil and Water Conservation, Vol 37, No 1, p 45-50, January/February, 1982. 4 Fig, 1 Tab, 13 Ref.

Descriptors: *Maps, *Information systems, *Water quality management, Land use, Lake Erie Basin, Soil properties, Watershed management, Cultivation, Land Resource Information System, Data collections, Sediment transport, Phosphorus, Nonpoint pollution sources.

A Land Resource Information System (LRIS) was devised by the U.S. Army Corps of Engineers Lake Erie Wastewater Management Study (LEWMS) for water resources planning in the Lake Erie Basin. LRIS is a variable size (4-36 ha) system which encodes each cell for each parameter at a randomized point location within each cell. Information included is land use or cover, soil characteristics, and political and hydrological boundaries. Data were supplied from several agencies and previous studies. The LRIS can produce maps or tables. Color maps can be developed for the entire basin or any division down to the township level. These maps clearly show soil types, crop intensity, soil texture, and slope. Data from LRIS can be used in the ANSWERS model to simulate sediment and phosphorus transport under different conservation practices. (Cassar-FRC)

RECORDING RAINGAGE MODIFICATIONS,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
J. D. Greer.
Journal of Soil and Water Conservation, Vol 37, No 1, p 63-64, January/February, 1982. 2 Fig, 1 Ref.

Descriptors: *Rain gages, *Charts, *Measuring instruments, Precipitation, Rainfall, Experimental design.

Evaporation from a rain gage was minimized by installing a U-trap, similar to a lavatory drain trap, between the collecting funnel and the 5-quart jar with screw-on top. A small hole in the top relieved air pressure as rainwater flowed into the container. No evaporation from the rain gage between storms was evident. An FW-1 type water stage recorder was modified to record rain days for one month. A tipping bucket was constructed to indicate the date of rainfall starts and stops on a recording chart. (Cassar-FRC)

NORMALITY OF HYDROLOGICAL DATA,
Asian Inst. of Tech., Bangkok (Thailand).
H. N. Phien, A. Sunchindah, and D. Patnaik.
Water Resources Bulletin, Vol 18, No 1, p 37-42, February, 1982. 6 Tab, 24 Ref.

Descriptors: *Hydrologic data, *Statistical analysis, Mathematical studies, *Stochastic process, Hydrologic models, Analysis of variance, Probabilistic process.

Although the normal distribution plays an important role in stochastic hydrology in which statistical techniques have been extensively employed, the assessment of the normality of hydrological data has been based largely on subjective judgments. Three computationally simple statistical tests are suggested for assessing the normality assumption with respect to hydrological sequences. Statistical tests for normality include standard moment ratios, analysis of variance tests, and tests based on probability plots. These statistical tests were applied to monthly and annual stream flow data from six stations to assess the validity of the assumption that these data, their square roots or logarithms are normal. This analysis showed that, for the stream flow data used, at least one of the three annual sequences (original, square root, and logarithmic) can be treated as normal; monthly stream flows cannot always be represented by normal distributions; and the square root and logarithmic transformations cannot render all the 12 monthly stream flow sequences normal. These results indicate that different transformations may be required for different months and that the assumption of normality for monthly stream flows under only one of the two transformations is less realistic. ON HYDROLOGICAL DATA NEEDS IN CANADA,
British Columbia Univ., Vancouver. Dept. of Geography.
M. Church, and R. Kellerhals.
Canadian Water Resources Journal, Vol 5, No 4, p 1-24, 1980. 4 Fig, 1 Tab, 31 Ref.

Descriptors: *Data collections, Water management, *Streamflow, *Hydrologic data, *Canada, Rivers, Ice, Glacial streams, Stream gages, Gaging stations, Channel morphology, Sediments, Regional analysis, Data interpretation, Planning.

Canada's abundant surface water resources are different in some respects (extreme temperatures, highly seasonal runoff, postglacial topography, and gravel beds) from rivers in other parts of the world for which much hydrologic data has been collected and studied. Present sources of data for Canada rivers are stream gaging stations, engineering histories, and special studies. Existing data must be presented in more usable form, for example, listing data not by calendar year but by a period suitable for the hydrologic conditions, tabulation of extreme streamflows by type, routine frequency anal-

ysis by a central group, flow probability and flow duration summaries, indication of long-term trends, a central source for all data summaries, and indication of precision of data. Development of a hydrological data base should include more reliable and sophisticated stream gaging equipment, a systematic program to study ice formation and decay and problems caused by ice, documentation of river channel morphology, field studies of extreme events and biophysical processes, compilation of regional knowledge, and extension of suspended sediment monitoring sites. Suggestions are given for educational and institutional changes necessary to implement these changes in hydrological data collections. (Cassar-FRC)

TELEMETRY AND REAL TIME ENVIRONMENTAL DATA ACQUISITION (LA TELEMETRIE ET L'ACQUISITION EN TEMPS REEL DES DONNEES SUR L'ENVIRONNEMENT),
C. Pesant.
Canadian Water Resources Journal, Vol 5, No 4, p 25-39, 1980. 4 Fig, 3 Tab. English abstract.

Descriptors: *Remote sensing, *Telemetry, *Data acquisition, Satellite technology, Data collections, Hydrologic data collections, Quebec, Monitoring, Computers, Forecasting.

Quebec's telemetry network, which dates back to 1977, consists of 100 stations for collection of meteorological and hydrologic data. Communication in the system is by telephone lines in urban and rural areas and by the satellite GOES in more remote regions. A minicomputer, Nova 4, coordinates data acquisition and dissemination. Average efficiencies of the 100 stations were 96-99% during the year starting September 1979. Objectives of the network are to inventory surface waters and climate, to forecast water levels, to aid in design of reservoirs and hydroelectric stations, and to protect forests. Users of the information include Environment Quebec, Quebec Energy and Resources, James Bay Energy Society, and Alcan Canada Limited. (Cassar-FRC)

ON THE SAMPLING VARIANCE OF RAINGAGE NETWORKS,
Bureau of Reclamation, Denver, CO. Div. of Atmospheric Resources Research.
B. A. Silverman, L. K. Rogers, and D. Dahl.
Journal of Applied Meteorology, Vol 20, No 12, p 1468-1478, December, 1981. 3 Fig, 5 Tab, 24 Ref.

Descriptors: *Rainfall distribution, *Measuring instruments, Model studies, Variability, Rainstorms, Precipitation rate, Precipitation.

The sampling variance of raingage networks is examined, and this variance is related quantitatively to both the density of raingages and the characteristics of the isohyetal pattern. The variance due to sampling results from the necessity of estimating areal rainfall values from point measurements of a storm footprint that contains spatial gradients. This is especially true for convective storms. Depending on how a storm passes over the gage network, the precipitation is usually either under-or overestimated. A computer model of raincell isohyetal patterns is used to assess the sampling variance. The coefficient of variation was found to increase with decreasing gage density and increasing precipitation gradient. Contrary to the sampling error studies of other investigators, it was found that the mean precipitation remained unbiased as the gage density decreased, but its standard deviation increased. The theoretical isohyetal patterns were then related to observed isohyetal maps and the characteristics of their structure. The observations suuggested a tendency for the precipitation gradient to be steepest, increasing rapidly toward the storm precipitation maximum, in short-duration convective storms of small areal extent. More uniform precipitation gradients tend to be found in steady type rains and large, long-lasting storms. Expressed in terms of the percentage of storm area containing 50% of the precipitation volume, the precipitation gradient varied from 15 to 30%. It was also found that convective raincell patterns tended to be elliptical in shape. (Baker-FRC)

F. G. Gay, and D. F. Delaney.
Massachusetts Hydrologic-Data Report No 22, 1981. 22 p, 1 Plate, 5 Tab, 21 Ref.

Descriptors: *Hydrologic data, *Groundwater, Test wells, Well logs, Water level, Chemical analysis, *Massachusetts, *Shawsheen River basin, Borings.

The Shawsheen River basin drains a 77-square-mile area into the Merrimack River. The basin is northwest of the Boston metropolitan area in eastern Massachusetts within Essex and Middlesex Counties. This report contains hydrologic data for all, or parts of, the cities and towns of Andover, Bedford, Billerica, Burlington, Concord, Lawrence, Lexington, Lincoln, North Andover, Tewksbury, Wilmington, and Woburn. Information in this report includes well, test-well, and boring data; chemical analyses of ground water complied from 1972 to 1974; and a list of publications containing ground-water-level records. HYDROGEOLOGIC DATA COLLECTED FROM THE KISSIMMEE PLANNING AREA, SOUTH FLORIDA WATER MANAGEMENT DISTRICT,
Geological Survey, Tallahassee, FL. Water Resources Div.
D. E. Reece, R. Belles, and M. P. Brown.
South Florida Water Management District Report, 1981. 192 p, 3 Fig, 6 Tab, 31 Ref.

Descriptors: *Hydrologic data, *Groundwater, *Water quality, *Water management, Aquifers, *Geohydrology, Potable water, Water use, Wells, Water level, Well logs, Specific capacity, Water analysis, *Florida, Kissimmee, Floridan aquifer.

The Floridan aquifer is the primary source of potable water in the populated northern part of the Kissimmee Planning Area of central Florida and the major source of water for agricultural use throughout the area. Because of the importance of the Floridan aquifer in the area, a reconnaissance study was conducted to collect data necessary to describe the geology, hydrologic properties, and water quality of the aquifer. This report contains the following data: well descriptions for 130 wells; water-level measurements for 122 wells; water-level hydrographs for 7 wells; geologic descriptions of drill cuttings for 7 wells; and geophysical logs for 43 wells. (USGS)

HYDROLOGIC DESCRIPTION OF LAKE JACKSON, SEBRING, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
K. M. Hammett.
Geological Survey Open-File Report 81-494 (WRI), 1981. 1 Sheet, 10 Fig, 2 Tab, 8 Ref.

Descriptors: *Lakes, *Limnology, *Lake morphometry, *Hydrologic budget, Lake stages, Hydrologic data, Surface-groundwater relations, Bathymetry, Water quality, Chemical analysis, *Florida, Sebring, *Lake Jackson.

Available data were evaluated to document hydrologic conditions in the Lake Jackson basin, Florida. Bathymetric data indicate numerous dredged

holes around the perimeter of the lake. Away from the dredged holes, a firm sand bottom slopes gradually from the shore to a maximum depth of 22 feet. Lake Jackson's stage declined 3 feet from 1970 to 1973 and has remained below normal since that time. Rainfall was below average from 1970 to 1973, but the lake-level decline did not result solely from deficient precipitation. A water-budget analysis of the lake indicates that channelization downstream and groundwater withdrawals contributed significantly to the decline. Lake Jackson is used extensively for recreation. Available water-quality data indicate suitable conditions for recreation and the propagation and management of fish and wildlife. (USGS)

HYDROLOGY OF THE WINTER HAVEN CHAIN OF LAKES, POLK COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
W. C. Sinclair, and R. C. Reichenbaugh.
Geological Survey Open-File Report 81-212 (WRI), 1981. 1 Sheet, 12 Fig, 1 Tab, 3 Ref.

Descriptors: *Lakes, Lake basins, Lake stages, *Limnology, Bathymetry, Geohydrology, Hydrologic data, Rainfall, Surface-groundwater relations, Pumpage, Aquifers, Water level, Hydrographs, Maps, *Florida, *Polk County, *Winter Haven Chain of Lakes, Floridan aquifer.

Fourteen interconnected lakes in and around the city of Winter Haven, Polk County, Fla., form the Winter Haven Chain of Lakes. Levels of the lakes during the spring of 1976 were at a record low stage for the 31 years of record. During 1960-76, rainfall had been below average for all but 2 years, and departure from average rainfall totaled 72.34 inches. Fluctuations in stage of Lake Howard, representative of the chain, and of Lake Otis, the nearest isolated lake that has a reasonably long record of stage, were compared with other hydrologic variables. Analyses of lake stage and rainfall records indicate that deficient rainfall has been the key factor in the decline of lake levels in the area. Manipulation of lake levels, pumpage from the lakes and underlying aquifer, and urbanization of the watershed probably have affected the lakes as well, but records are not available to determine the significance of their effects. The surficial aquifer drains to the lakes. Water level in the underlying Floridan aquifer is everywhere lower than in any of the lakes, thus water moves from the lakes and surficial aquifer through the confining clay layer to the Floridan aquifer. (USGS)
W82-04977

MAP SHOWING THE POTENTIOMETRIC SURFACE OF THE AQUIA AQUIFER, MAY 19-23, 1980,
Geological Survey, Towson, MD. Water Resources Div.
F. Chapelle, D. Drummond, and T. Curley.
Available from the OFSS, USGS Box 25425, Fed Ctr., Denver, CO 80225. Price: $1.00 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-416, 1981. 1 Sheet.

Descriptors: Maps, *Potentiometric level, *Aquifers, *Observation wells, Groundwater level, Coastal plains, *Maryland, *Aquia aquifer.

The map is based on water level measurements made May 19-23, 1980. The well network used included 83 wells which have been screened in the Aquia aquifer (Aquia Formation of Paleocene Age). Highest levels of the potentiometric surface, 20 to 35 feet above sea level, were measured near the outcrop or subcrop of the aquifer in the topographically high areas of Anne Arundel and Prince Georges Counties. The potentiometric surface slopes to the southeast. Four separate and extensive cones of depression have developed in the potentiometric surface in the vicinities of Lexington Park, Leonardtown, Prince Frederick, and Chesapeake Beach. The cones of Leonardtown and Lexington Park seem to be merging. (USGS)

COMPILATION OF HYDROLOGIC DATA FOR THE EDWARDS AQUIFER, SAN ANTONIO AREA, TEXAS, 1934-79.
Geological Survey, San Antonio, TX. Water Resources Div.
Edwards Underground Water District Bulletin 39, October, 1981. 133 p, 4 Fig, 8 Tab, 82 Ref.

Descriptors: *Hydrologic data, *Aquifers, *Groundwater, Groundwater recharge, Wells, Springs, Discharge measurement, Water level, Groundwater storage, Water sampling, Water quality, Texas, *San Antonio area, *Edwards aquifer.

The average annual ground-water recharge to the Edwards aquifer in the San Antonio area, Texas, from 1934 through 1979, was 598,800 acre-feet. The recharge in 1979 was 1,117,800 acre-feet, which was the fifth highest estimated recharge since 1934. A maximum annual recharge of 1,711,200 acre-feet occurred in 1958, and a minimum annual recharge of 43,700 acre-feet occurred in 1956. The estimated annual discharge by wells and springs in 1979 was 914,500 acre-feet. A maximum annual discharge of 960,900 acre-feet occurred in 1977, and a minimum annual discharge of 388,800 acre-feet occurred in 1955. During 1979, water levels in wells in the Edwards aquifer fluctuated near record highs; consequently, the volume of ground water in storage in the aquifer also was near the record high. Analyses of water samples from 77 wells and 3 springs show no evidence of significant degradation of water quality in the Edwards aquifer, and the data show no trend of degradation in water quality. (USGS)
W82-04987

FLOOD AND DEBRIS FLOOD HAZARDS MAP, CARSON CITY QUADRANGLE,
Geological Survey, Carson City, NV. Water Resources Div.
T. Katzer, and C. V. Schroer.
Available from Nev. Bur. of Mines and Geo. Univ. of Nevada Reno, Nevada 89557, Price: $2.50. Nevada Bureau of Mines and Geology Map 1A1, 1981. 1 Sheet.

Descriptors: *Maps, *Floods, *Detritus, *Hazards, Flood peak, Flood plains, Flood flow, Erosion, Deposition, *Nevada, *Carson City quadrangle.

This map shows the flood and debris hazards on the Carson City quadrangle, Nevada. Estimates of the 100-year floodflow were made and the corresponding flood plains were outlined on the map for the principal drainages in the area. Degrees of hazard were assigned to the flood plains of these streams on the basis of floodflows and potential debris movement. (USGS)
W82-05217

TEST-HOLE DATA FOR THE EDWARDS AQUIFER IN THE SAN ANTONIO AREA, TEXAS,
Geological Survey, Houston, TX. Water Resources Div.
T. A. Small, and R. W. Maclay.
Texas Department of Water Resources LP-171, January 1982. 153 p, 9 Fig, 38 Tab, 21 Ref.

Descriptors: *Test holes, *Core drilling, *Aquifers, Data collections, Porosity, Permeability, Mineralogy, Water management, *Texas, San Antonio area, *Edwards aquifer, *Geohydrology.

This report contains descriptive geologic data collected by the U.S. Geological Survey during a test-hole program to develop a factual concept of the distribution of porosity and permeability within the framework of the Edwards aquifer in the San Antonio area, Texas. The test-hole program produced more than 4,000 feet (1,219 meters) of rock core from eight holes during May 1972 to April 1974. The selection of test-hole sites was based on considerations of possible water management problems, geologic conditions, and the limitations of the drilling and coring equipment. Cores were examined for composition, color, hardness, grain size, grain type, sedimentary structure, pore shape and size, and total porosity. Laboratory tests were used to determine porosity, pore-size distribution, permeability, grain density, formation factor, and mineralogy. (USGS)
W82-05218

BEDROCK AQUIFERS IN THE LOWER DIRTY DEVIL RIVER BASIN AREA, UTAH, WITH

SPECIAL EMPHASIS ON THE NAVAJO SANDSTONE,
Geological Survey, Salt Lake City, UT. Water Resources Div.
J. W. Hood, and T. W. Danielson.
Available from Utah Dept. of Natural Res. Div. of Water Rights 1636 West North Temple Room 220 Salt Lake City, Utah 84116. Utah Department of Natural Resources Technical Publication No 68, 1981. 143 p, 22 Fig, 4 Plates, 14 Tab, 48 Ref.

Descriptors: *Bedrock, *Aquifers, *Aquifer characteristics, *Surface-groundwater relations, Precipitation, Rainfall disposition, Hydrologic budget, Wells, Well logs, Water level, Well yields, Groundwater recharge, Groundwater movement, Groundwater storage, Water quality, Chemical analysis, Salinity, *Utah, *Dirty Devil River basin, Navajo Sandstone.

The lower Dirty Devil River basin area in southeastern Utah has an area of about 4,300 square miles. Precipitation is the main source of water and averages 1.55 million acre-feet annually in the long term. Rocks in the area range from Precambrian to Holocene. The section of sedimentary rocks ranges from 7,300 to 23,000 feet in thickness. Major aquifers are the Entrada, Navajo, Wingate, and Coconino Sandstones and rocks of Mississippian age. They contain fresh to briny water. Their permeability is affected by folding, faulting, and igneous intrusion. The annual water supply averages 1.6 million acre-feet, of which an estimated 96% is consumed by evapotranspiration. The estimated long-term annual gross ground-water recharge is 34,000 acre-feet, of which 5,000 acre-feet recharges the Navajo Sandstone. Recoverable fresh to moderately saline water stored in the Navajo, Wingate, and Coconino Sandstones is estimated to be 210 million acre-feet, of which 89 million acre-feet is stored in the Navajo alone. Long-term withdrawals from the Navajo Sandstone, of up to 12,000 gallons per minute, probably would diminish the flow of the Dirty Devil River, but would have a negligible effect on the volume of ground water in storage or the flow of the Colorado River. (USGS)
W82-05220

HYDROLOGIC RECONNAISSANCE OF THE SOUTHERN GREAT SALT LAKE DESERT AND SUMMARY OF THE HYDROLOGY OF WEST-CENTRAL UTAH,
Geological Survey, Salt Lake City, UT. Water Resources Div.
J. S. Gates, and S. A. Kruer.
Available from Utah Dept. of Natural Res. Div. of Water Rights 231 East 400 South Salt Lake City, Utah 84111. Utah Department of Natural Resources Technical Publication No 71, 1981. 55 p, 4 Fig, 4 Plates, 10 Tab, 38 Ref.

Descriptors: *Hydrologic data, *Hydrologic budget, *Groundwater, *Water quality, *Surface water, Arid climates, Evaluation, Water resources development, Potential water supply, Aquifer characteristics, Groundwater movement, Water storage, Wells, Springs, Well data, Chemical analysis, *Utah, *Great Salt Lake Desert, West-central Utah.

The report is the last of 19 hydrologic reconnaissances of the basins in western Utah. The purposes of this series of studies are (1) to analyze available hydrologic data and describe the hydrologic system, (2) to evaluate existing and potential water-resources development, and (3) to identify additional studies that might be needed. Part 1 of the report gives an estimate of recharge and discharge, an estimate of the potential for water-resources development, and a statement on the quality of water in the southern Great Salt Lake Desert part of west-central Utah. Part 2 deals with the same aspects of west-central Utah as a whole. Part 2 also summarizes the evidence of inter-basin groundwater flow in west-central Utah and presents a theory for the origin of the water discharged from Fish Springs. Annual ground-water recharge is about 241,000 acre-feet in west-central Utah and about 84,000 acre-feet in the southern Great Salt Lake Desert. Annual ground-water discharge is about 259,000 acre-feet from west-central Utah and about 84,000 acre-feet from the southern desert. Ground water in west-central Utah ranges from fresh in unconsolidated fill under the margins of the basins bordered by higher mountain ranges to briny under the mud- and salt-flat areas. About 17.4 million acre-feet of ground water, of which possibly two-thirds is fresh, is stored in the upper 100 feet of saturated basin fill in west-central Utah. Ground water flows into west-central Utah and between basins through consolidated rock. Most of the 26,000 acre-feet per year discharged at Fish Springs probably is recharged along the flanks of the Deep Creek Range and moves as interbasin flow through Snake Valley and possibly Tule Valley to Fish Springs Flat. (USGS)
W82-05221

CHEMICAL CHARACTER OF WATER IN THE RED RIVER ALLUVIAL AQUIFER, LOUISIANA,
Geological Survey, Baton Rouge, LA. Water Resources Div.
M. S. Whitfield, Sr.
Geological Survey Water Resources Investigation, Open-File Report 80-1018, 1980. 95 p, 3 Fig, 21 Plates, 5 Tab, 41 Ref.

Descriptors: *Water quality, *Groundwater, *Hydrologic data, *Chemical properties, Alluvial aquifers, Aquifer characteristics, Rainfall, *Groundwater recharge, Groundwater movement, Wells, Water level, Water yield, Chemical analysis, Pesticides, Maps, *Louisiana, *Red River Valley, Black River, Dissolved solids.

The Red River alluvial aquifer underlies 2,000 square miles in the Red River Valley of Louisiana and is the only source of fresh ground water in most of the valley. The aquifer consists mainly of sand and gravel and ranges from 40 to 150 feet in thickness. Recharge is by rainfall, by lateral movement of water from adjacent older formations, and by upward discharge from underlying aquifers. These varied sources of recharge cause both areal and vertical differences and variations in water quality. Water levels generally range from about 0 to less than 30 feet below land surface, and the aquifer is capable of yielding 1,000-2,000 gallons per minute to individual wells. Water is typically of the calcium magnesium bicarbonate type. It ranges in hardness from less than 100 to 2,300 mg/L (milligrams per liter) but generally is between 200 and 600 mg/L. Dissolved iron concentrations ranges from about 0.3 mg/L to as high as 49 mg/L but generally is 1 to 10 mg/L. Dissolved sulfate concentrations generally range from 0.5 to 50 mg/L but locally exceed 250 mg/L. The dissolved chloride concentrations typically is less than 50 mg/L but locally exceeds 250 mg/L and is as high as 4,400 mg/L in a few areas. (USGS)
W82-05228

MAPS SHOWING GROUND-WATER CONDITIONS IN THE SAN SIMON WASH AREA, PAPAGO INDIAN RESERVATION, ARIZONA--1979,
Geological Survey, Tucson, AZ. Water Resources Div.
K. J. Hollett.
Geological Survey Water Resources Investigations Open-File Report 81-530, April 1981. 2 Sheets, 27 Ref.

Descriptors: *Maps, *Groundwater, *Water quality, *Wells, *Water level, Geohydrology, Alluvium, Water yield, Water use, Dissolved solids, Fluorides, Arsenic, Hydrographs, *Arizona, *Papago Indian Reservation, San Simon Wash.

The San Simon Wash area includes about 2,300 square miles in the Papago Indian Reservation in south-central Arizona. The area is characterized by low mountains separated by broad alluvial basins. The main water-bearing unit is the alluvium, which consists of clay, silt, sand, gravel, and small amounts of evaporite deposits. Properly constructed and developed wells in the basin fill generally yield more than 50 gallons per minute. Less than 50 gallons per minute is obtained from the crystalline and consolidated sedimentary rocks and from thin alluvial deposits in the mountains. In 1979 about 2,700 acre-feet of ground water was withdrawn for irrigation, public-supply, and livestock uses. The maps show depth to water, altitude of the water level, well depth, dissolved-solids, fluoride, and arsenic concentrations. Scale is 1:125,000. (USGS)
W82-05231

MAPS SHOWING GROUND-WATER CONDITIONS IN THE AGUA FRIA AREA, YAVAPAI AND MARICOPA COUNTIES, ARIZONA-1979,
Geological Survey, Tucson, AZ. Water Resources Div.
G. R. Littin.
Geological Survey Water Resources Investigations Open-File Report 81-804, June 1981. 2 Sheets, 13 Ref.

Descriptors: *Maps, *Groundwater, *Water level, *Wells, Geohydrology, Aquifers, Specific conductivity, Fluorides, *Arizona, Yavapai County, Maricopa County, Agua Fria area.

The Agua Fria area includes about 1,500 square miles in central Arizona. The water-bearing characteristics of the units that make up the aquifers vary greatly because of large differences in rock type and extent of fracturing. In order of decreasing yield potential, the major water-bearing units are the unconsolidated deposits, conglomerate, volcanic clastic deposits, and lake deposits. The minor water-bearing units consist of basaltic to rhyolitic volcanic rocks; and schist, gneiss, and granite. Ground-water development has been slight, and in 1978 about 3,200 acre-feet was withdrawn for irrigation, public supply, and domestic and stock uses. The maps show depth to water, altitude of the water level, well depth, and specific conductance and fluoride concentration in the water. Scale is 1:125,000. (USGS)

TECHNIQUES OF TREND ANALYSIS FOR MONTHLY WATER QUALITY DATA,
Geological Survey, Reston, VA.
R. M. Hirsch, J. R. Slack, and R. A. Smith.
Water Resources Research, Vol 18, No 1, p 107-121, February, 1982. 8 Fig, 5 Tab, 18 Ref.

Descriptors: *Water quality, *Monitoring, *Data interpretation, Statistical analysis, Trend analysis, Kendall tests, *Seasonal variation.

Three techniques (the seasonal Kendall test for trend, the seasonal Kendall slope estimator, and flow adjustment coupled with the seasonal Kendall test) are presented for identifying and quantifying monotonic trends in water quality with time. The methods overcome the difficulties produced by non-normal distribution, seasonality, flow relatedness, missing values, values below the detection limit, and serial correlation. The seasonal Kendall test for trends applies to data sets with seasonality, missing values, or values below the detection limit. The slope estimator test estimates trend magnitude. It estimates the slope of a linear trend more precisely than a regression estimator in the case of highly skewed data but less precisely where data are normal. The third procedure tests for changes over time in the relationship between constituent concentration and flow, overcoming the problems in identifying trends in water quality resulting from droughts. The flow adjusted concentration obtained can then be tested for trend by the seasonal Kendall test. These techniques eliminate subjectvie evaluation, which often concentrates on the extreme values rather than on the subtle but regular trends in the bulk of values nearer the mean. (Cassar-FRC)

USDA-SEA-AR-Beltsville, MD

GEOTECHNICAL APPLICATIONS OF LANDSAT IMAGE ANALYSIS OF BHAKRA DAM RESERVOIR, INDIA,
Indian Inst. of Tech., Bombay. Centre of Studies of Resources Engineering.
R. P. Gupta, and J. Bodechtel.
Remote Sensing of Environment, Vol 12, No 1, p 3-13, 1982. 5 Fig, 16 Ref.

Descriptors: *Remote sensing, *Reservoirs, *Monitoring, Bhakra Dam, India, Sutlej River, Landsat, Satellite technology, Geologic mapping, Mapping, rock properties, Water level, Geologic fractures, Drainage patterns, Water storage, Silting.

Analyses of Landsat images over the 240 m high concrete Bhakra Dam Reservoir on the Sutlej River, India, provided information on the geotechnical-structural nature of the area, reservoir monitoring, and silting hazards in the reservoir. Drainage patterns and tectonic features in the region were clearly discerned. A few well-developed lineaments run through the reservoir area, and some weakly marked structures are close to the dam site. No geologically recent structures approach the dam or reservoir. Determinations of temporal variations in lake area are most accurately done by digital processing of data from a 26 km length of stream bed which sensitively reflects lake levels. Landsat data identified 2 major silt-contributing zones in the reservoir. Both areas are characterized by low gradient slopes, wide valley sections, and mechanically weak rocks. Shales and clay-shales are found in Region A and fractures and defects in Region B. (Cassar-FRC)
W82-05612

FLOOD HAZARD MAPS AS PUBLIC INFORMATION: AN ASSESSMENT WITHIN THE CONTEXT OF THE CANADIAN FLOOD DAMAGE REDUCTION PROGRAM,
J. W. Handmer.
Canadian Water Resources Journal, Vol 5, No 4, p 82-110, 1980. 5 Fig, 4 Tab, 28 Ref.

Descriptors: *Public relations, *Maps, *Flood plains, Flood damage, Flood plain management, Flood plain zoning, Canadian Flood Damage Reduction Program, Information systems, Attitudes, Hazards, Carman, Manitoba, Oshawa, Ontario, Moosejaw, Saskatchewan, Publications, Risks, Zoning, Nonstructural alternatives.

The use of flood hazard maps as public information tools was evaluated by comparing attitudes of flood plain dwellers, commercial and industrial interests, and government officials with questionnaires and interviews. Carman, Manitoba (population 2400), Moosejaw, Saskatchewan (population 32,000), and Oshawa, Ontario (population 114,000) were chosen for the program. Results indicated that the substantially increased flood awareness among the group given flood hazard maps was not due to the maps alone but to increased publicity in all communications media. Methods of distributing maps which were not effective were passive distribution through public offices and libraries, printing copies of the maps in newspapers, and direct mailing. Although map dissemination is apparently ineffective in providing flood information to consumers, it is still a desirable practice. For maximum impact maps should involve local government officials, real estate agents, and mortgage companies. Maps should be visually striking, multicolored, and indicate each building clearly. Accompanying information should include brief, relevant explanations and mapping of a historic flood. (Cassar-FRC)
W82-05729

HYDROLOGY OF AREA 32, EASTERN REGION, INTERIOR COAL PROVINCE, INDIANA,
Geological Survey, Indianapolis, IN. Water Resources Div.
D. J. Wangsness, R. L. Miller, Z. C. Bailey, and C. Crawford.
Geological Survey Open-File Report 81-498 (WRI), August 1981. 76 p, 38 Fig, 12 Tab, 56 Ref, Append.

Descriptors: *Hydrologic data, *Water quality, *Groundwater, *Surface water, *Coal mines, Geohydrology, Hydrologic cycle, Climates, Land use, Soil classification, Indiana, Eastern region, Interior Coal Province.

Hydrologic and water-quality information from the coal region in parts of 11 counties in southwestern Indiana are summarized. Pennsylvanian and Mississippian bedrock are overlain by drift and till from the Kansan, Illinoian, and Wisconsinan glaciers that covered two-thirds of the area. Most of the coal is mined from Pennsylvanian coal units. As of 1978, more than 1-billion short tons of coal had been mined from the 11 counties. More than 12-billion short tons remained in reserve. During 1978, 17.8-million short tons were mined. Coal mining disturbs less than 1% of the land in the study area. Sixty-two percent of the land use is agricultural, and 29% is forested. More coal is mined in the southern and western parts of the study area than elsewhere. Surface water in these parts had lower pH and alkalinity than water in the north and east parts. Specific conductance and concentrations of sulfate, iron, and manganese in surface water were higher in the south and west than elsewhere. (USGS)
W82-05825

ANNUAL SUMMARY OF GROUND-WATER CONDITIONS IN ARIZONA, SPRING 1979 TO SPRING 1980.
Geological Survey, Tucson, AZ. Water Resources Div.
For primary bibliographic entry see Field 4B.
W82-05826

MAP SHOWING GROUND-WATER CONDITIONS IN THE SACRAMENTO VALLEY AREA, MOHAVE COUNTY, ARIZONA--1979,
Geological Survey, Tucson, AZ. Water Resources Div.
C. L. Pfaff, and D. M. Clay.
Geological Survey Open-File Report 81-418 (WRI), March 1981. 1 Sheet, 7 Ref.

Descriptors: *Maps, *Groundwater, *Wells, *Water level, *Water quality, Geohydrology, Aquifer characteristics, Specific conductivity, Fluorides, Water use, Groundwater potential, Hydrographs, *Arizona, Mohave County, Sacramento Valley area.

The Sacramento Valley area includes about 800 square miles in northwestern Arizona. The valley slopes gently southward and is filled with alluvium and volcanic rocks to depths of more than 4,000 feet. The alluvium is divided into three units--older, intermediate, and younger alluvium--and the volcanic rocks are divided into two units--older and younger volcanic rocks. The older alluvium is the main water-bearing unit and yields 20 to 1,300 gallons per minute of water to wells. In the Kingman area the younger volcanic rocks are about 1,400 feet thick and yield less than 1 to 300 gallons per minute. Ground-water development has been slight and, is general, has had little effect on water levels; however, water-level declines have occurred in places where ground water is withdrawn for industrial or municipal supplies. The map shows depth to water, altitude of the water level, well depth, specific conductance, and fluoride concentration. Hydrographs of the water level in selected wells and a table of historical pumpage also are included. Scale is 1:125,000. (USGS)
W82-05827

HYDROGEOLOGIC RECONNAISSANCE OF THE REPUBLICAN RIVER BASIN IN NEBRASKA,
Geological Survey, Lincoln, NE. Water Resources Div.
M. J. Ellis.
Geological Survey Open-File Report 81-531 (WRI), July 1981. 3 Sheets, 25 Ref.

Descriptors: *Maps, *Geohydrology, *Groundwater, *Aquifer characteristics, Bedrock, Water table, Water level, Water level fluctuations, Hydrologic data, *Nebraska, Republican River basin.

The Republican River basin in Nebraska includes about 9,710 square miles in the southwestern and south-central parts of the State. The principal sources of ground water in the basin are sand and gravel deposits overlying the Cretaceous bedrock. In the upland parts of the basin, these sands and gravels occur in both Pleistocene deposits and the Ogallala Formation. Along the Republican River valley the sands and gravels occur in undifferentiated Holocene and Pleistocene deposits. Information mapped includes: configuration of the Cretaceous bedrock surface and the configuration of the spring 1977 water table (scale, 1:250,000); and approximate outcrop of Cretaceous bedrock and approximate extent of White River Group (scale 1:1,000,000). CHLORIDE AND TOTAL HARDNESS CONCENTRATIONS OF WATER FROM THE UPPER PART OF THE FLORIDAN AQUIFER IN ST. JOHNS COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
P. S. Hampson, and E. C. Hayes.
Geological Survey Open-File Report 81-907 (WRI), 1982. 1 Sheet, 4 Fig, 3 Tab, 15 Ref.

Descriptors: *Groundwater, *Water quality, *Aquifers, *Potentiometric level, Geohydrology, Data collections, Chlorides, Hardness, Salinity, Pumpage, Irrigation, *Florida, St. Johns County, Floridan aquifer.

Data collected from 1976 to 1979 indicate large water-quality variations in the upper 300 feet of the Floridan aquifer in St. Johns County, Florida. Chloride concentrations range from less than 10 milligrams per liter in the northwestern part of the county to more than 1,000 milligrams per liter in the southeast and extreme southwest. Total hardness concentrations range from 110 milligrams per liter in the northwest to 1,700 milligrams per liter in the southeast. In most of the county, high chloride and total hardness concentrations indicate the presence of saline water that entered the aquifer during the Pleistocene Epoch and has not been flushed out. Water quality in the aquifer has also been influenced by submarine discharge in the southeast and by heavy pumpage for irrigation in the southwest. High total hardness concentrations not accompanied by high chloride values in the western part of the county may be structurally controlled or may indicate the presence of gypsum evaporite beds in the upper 300 feet of the aquifer. HYDROGEOLOGIC SECTIONS THROUGH LEE COUNTY AND ADJACENT AREAS OF HENDRY AND COLLIER COUNTIES, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
D. H. Boggess, T. M. Missimer, and T. H. O'Donnell.
Geological Survey Open-File Report 81-638 (WRI), 1981. 1 Sheet, 6 Fig, 5 Ref.

Descriptors: *Groundwater, *Geohydrology, *Aquifers, *Water table, Aquifer characteristics, Geologic formations, Wells, Water yield, Water quality, *Florida, Lee County, Hendry County, Collier County.

The freshwater underlying Lee, western Hendry, and northern Collier Counties occurs within the marine terrace sands, the Fort Thompson, Caloosahatchee, Tamiami, and Hawthorn Formations. These are, respectively, the water-table aquifer, an aquifer in the Tamiami Formation, and an aquifer in the upper part of the Hawthorn Formation. These aquifers are separated by clay, marl, and marly limestone. Wells tapping the water-table aquifer are commonly less than 50 feet deep, with yields ranging from 5 to 500 gallons per minute. The water quality in the aquifer is usually good, except for iron, which generally exceeds 1 milligram per liter, and color, which ranges from 30 to 600 Platinum-Cobalt units. Wells tapping the Tamiami aquifer range in depth from about 60 to 300

feet; most are less than 100 feet deep. Yields range from 20 to 500 gallons per minute. The water quality in the Tamiami aquifer is good, except where affected by leakage from deep artesian wells. Wells tapping the upper Hawthorn aquifer range in depth from about 100 to 300 feet. Yields range from 10 to 500 gallons per minute. The water quality from the upper Hawthorn aquifer is good, except in areas where upward leakage from the deep artesian aquifer has occurred. (USGS)

HYDROLOGY OF AREA 3, EASTERN COAL PROVINCE, PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
W. J. Herb, L. C. Shaw, and D. E. Brown.
Geological Survey Open-File Report 81-537 (WRI), September 1981. 88 p, 65 Fig, 26 Tab, 29 Ref, Append.

Descriptors: *Hydrologic data, *Water quality, *Groundwater, *Surface water, *Coal mines, Acid mine drainage, Water pollution sources, Streams, Flow characteristics, Chemical analysis, Metals, Permits, *Pennsylvania, Eastern Coal Province, Ohio River basin.

Hydrologic data are presented for area 3 of the Eastern Coal Province, 4,077 square miles of the lower Allegheny River basin in western Pennsylvania. Seventy-three streams were sampled three times during the 1979 and 1980 water years for specific conductance, pH, acidity, alkalinity, dissolved and total iron, dissolved and total manganese, dissolved sulfate, and dissolved solids. Benthic invertebrate populations were determined and botom material samples were analyzed for metals. Sixteen streams had pH, acidity, alkalinity, total iron, total manganese, and dissolved sulfate indicative of acid-mine drainage. These streams were most common in the Redbank and Blacklick Creek basins and in the Conemaugh and lower Kiskiminetas River basins. Benthic invertebrates were not found in 11 of 64 streams sampled. An additional 13 streams had low benthic invertebrate diversity indices. Low diversity indices were most common in the southern part of area 3. Low flow, mean flow, peak flow, and flow duration data are presented for gaging stations in area 3. Techniques for estimating these data for ungaged sites are presented and referenced. The functions of, and access to, the National Water Data Exchange, National Water Data Storage and Retrieval System, and Office of Water Data Coordination are explained. (USGS)

HYDROLOGY OF AREA 25, EASTERN REGION, INTERIOR COAL PROVINCE, ILLINOIS,
Geological Survey, Urbana, IL. Water Resources Div.
E. E. Zuehls, G. L. Ryan, D. B. Peart, and K. K. Fitzgerald.
Geological Survey Open-File Report 81-636 (WRI), September 1981. 66 p.

Descriptors: *Hydrologic data, Water quality, *Groundwater, *Surface waters, *Coal mines, Geohydrology, Acid mine drainage, Water pollution sources, Strip mines, Soil classification, Agriculture, Chemical analysis, *Illinois, Interior Coal Province, Eastern region.

The eastern region of the Interior Coal Province has been divided into 11 hydrologic study areas. Area 25, located in west-central Illinois, includes the Spoon River and small tributaries to the Illinois River. Pennsylvanian age rocks underlie most of the study area. Illinois, with the largest reserves of bituminous coal, is second only to Montana in total coal reserves. Loess soils cover most of the study area. Agriculture is the dominant land use. Surface water provides 97% of all the water used. Precipitation averages 34 to 35 inches. Water-quality data has been collected at over 31 sites. Analysis for specific conductance, pH, alkalinity, iron, manganese, sulfate and many trace elements and other water-quality constituents have been completed. These data are available from computer storage through the National Water Data Storage and Retrieval System (WATSTORE). (USGS)
W82-05832

HYDROLOGY OF AREA 4, EASTERN COAL PROVINCE, PENNSYLVANIA, OHIO, AND WEST VIRGINIA,
Geological Survey, Columbus, OH. Water Resources Div.
D. K. Roth, and M. J. Engelke, Jr.
Geological Survey Open-File Report 81-343 (WRI), July, 1981. 62 p, 41 Ref, 3 Append.

Descriptors: *Hydrologic data, *Water quality, *Groundwater, *Surface water, *Coal mines, Geohydrology, Acid mine drainage, Water pollution sources, Erosion, Sedimentation, Streams, Flow characteristics, *Ohio, *Pennsylvania, *West Virginia, Eastern Coal Province, Ohio River basin.

Area 4 (one of the 24 hydrologic areas defining the Eastern Coal Province) is located at the northern end of the Eastern Coal Province in eastern Ohio, northern West Virginia, and western Pennsylvania. It is part of the upper Ohio River basin, which includes the Beaver, Mahoning, and Shenango Rivers. The area is underlain by rocks of the Pottsville, Allegheny, Conemaugh, Monongahela Groups (or Formations) and Dunkard Group. Area 4 has a temperate climate with an annual average rainfall of 38 to 42 inches, most of its area is covered by forest. The soils have a high erosion potential where the vegetation cover is removed. In response to Public Law 95-87, 132 sites were added to the existing surface-water data-collection network in area 4. At these added sites, collected data includes discharge, water quality, sediment, and biology. The data are available from computer storage through the National Water Data Exchange (NAWDEX) or the published annual Water Resources Data reports for Ohio, Pennsylvania, and West Virginia. Hydrologic problems related to mining are: (1) Erosion and increased sedimentation, and (2) degradation of water quality. Erosion and sedimentation are associated chiefly with surface mining. Sediment yields increase drastically when vegetation is removed from the highly erosive soils. Degradation of water quality can be caused by acid-mine drainage from underground and surface mining. More than half the acid-mine drainage effluent in area 4 comes from underground mines. The rest seeps from abandoned surface mines. Usually in reclaimed surface mines the overburden is replaced in such a short time after the coal is taken out that oxidation of acid-forming minerals, commonly pyrite or marcasite, is not complete or is neutralized by the buffering action of calcareous minerals in the soils. (USGS)

HYDROLOGY OF AREA 5, EASTERN COAL PROVINCE, PENNSYLVANIA, MARYLAND, AND WEST VIRGINIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
W. J. Herb, L. C. Shaw, and D. E. Brown.
Geological Survey Open-File Report 81-538 (WRI), September 1981. 92 p, 60 Fig, 22 Tab, 37 Ref, Append.

Descriptors: *Hydrologic data, *Water quality, *Groundwater, *Surface water, *Coal mines, Acid mine drainage, Water pollution sources, Streams, Flow characteristics, Chemical analysis, Metals, Permits, *Pennsylvania, *Maryland, *West Virginia, Eastern Coal Province, Ohio River basin.

Hydrologic data are presented for area 5 of the Eastern Coal Province, the 7,384 square-mile Monongahela River basin in western Pennsylvania, western Maryland, and north-central West Virginia. One hundred thirty-four streams were sampled about three times during the 1979 and 1980 water years for specific conductance, pH, acidity, alkalinity dissolved and total iron, dissolved and total manganese, dissolved sulfate, and dissolved solids. Benthic invertebrate populations were determined and bottom material samples were analyzed for metals. Eleven streams had pH, acidity, alkalinity, total iron, total manganese, and dissolved-sulfate levels indicative of acid-mine drainage. These streams were most common in the Tygart Valley River basin, although indicators of acid-mine drainage were found throughout the Monongahela basin. No benthic invertebrates were found in 25 of 129 streams sampled. Such streams were most common in the Cheat and Tygart Valley River basins. Low flow, mean flow, peak flow, and flow duration data are presented for gaging stations in area 5. Techniques for estimating these data for ungaged sites are presented and referenced. The functions of, and access to, the National Water Data Exchange, WATSTORE, and indexes to water-data activities in coal provinces are presented. (USGS)
W82-05834

HYDROLOGY OF AREA 18, EASTERN COAL PROVINCE, TENNESSEE,
Geological Survey, Nashville, TN. Water Resources Div.
V. J. May.
Geological Survey Open-File Report 81-492 (WRI), August 1981. 78 p, 30 Ref. 3 Append.

Descriptors: *Hydrologic data, *Water quality, *Groundwater, *Surface water, *Coal mines, Streams, Acid mine drainage, Geohydrology, Chemical analysis, Permits, *Tennessee, Eastern Coal Province, Cumberland River basin.

The Eastern Coal Province is divided into 24 hydrologic reporting areas. This report describes the hydrology of area 18 which is located in the Cumberland River basin in central Tennessee near the southern end of the Province. Hydrologic information and sources are presented as text, tables, maps, and other illustrations designed to be useful to mine owners, operators, and consulting engineers in implementing permit applications that comply with the environmental requirements of the 'Surface Mining Control and Reclamation Act of 1977.' Area 18 encompasses parts of three physiographic regions; from east to west the Cumberland Plateau, Highland Rim, and Central Basin. The Plateau is underlain by sandstones and shales, with thin interbedded coal beds, of Pennsylvanian age. The Highland Rim and Central Basin are underlain by limestone and dolomite of Mississippian age. Field and laboratory analyses of chemical and physical water-quality parameters of streamflow samples show no widespread water quality problems. Some streams, however, in the heavily mined areas have concentrations of sulfate, iron, manganese, and sediment above natural levels, and pH values below natural levels. Mine seepage and direct mine drainage were not sampled. Ground water occurs in and moves through fractures in the sandstones and shales and solution openings in the limestones and dolomites. Depth to water is variable, ranging from about 5 to 70 feet below land-surface in the limestones and dolomites, and 15 to 40 feet in the coal-bearing rocks. The quality of ground water is generally good. Locally, in coal-bearing rocks, acidic water and high concentrations of manganese, chloride, and iron have been detected. (USGS)

SUMMARY OF AVAILABLE DATA ON SURFACE WATER, STATE OF HAWAII. VOLUME I: ISLAND OF KAUAI,
Geological Survey, Honolulu, HI. Water Resources Div.
I. Matsuoka.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80025, Price: $75.25 in paper copy, $4.50 in microfiche. Geological Survey Open-File Report 81-1056, November 1981. 537 p, 2 Plates, 5 Ref.

Descriptors: *Data collections, *Surface water, *Water quality, *Streamflow, Flow characteristics, Flow duration, Discharge measurement, Gaging station, Sites, Sedimentation, Phytoplankton, *Hawaii, Kauai.

This report presents statistical summaries of surface-water discharge records and tabulations of surface-water-quality parameters at data-collection sites in Kauai, Hawaii. Data presented in this

report are mainly in tabular format. They consist of concise site description and information, flow-duration table, various monthly and annual discharges, lowest and highest mean discharges for each year for specified numbers of consecutive days, statistics for monthly and annual mean discharges, and tabulation and summary of surface-water-quality data. Water-quality parameters include sediment and phytoplankton data. Maps with surface-water data-collection sites, plotted with their respective hydrologic boundaries, are included. These data provide the information needed for deriving correlative associations and sound estimates that can be used in reaching surface-water management and control decisions. (USGS)
W82-05836

MAP SHOWING HOW THE POTENTIOMETRIC SURFACE OF THE MAGOTHY AQUIFER OF AUGUST 1980 DIFFERED FROM THE POTENTIOMETRIC SURFACE OF SEPTEMBER 1977, IN SOUTHERN MARYLAND,
Geological Survey, Towson, MD. Water Resources Div.
F. K. Mack, J. C. Wheeler, and S. E. Curtin.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $19.75 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-631, 1981. 1 Sheet.

Descriptors: *Maps, *Potentiometric level, *Aquifers, *Observations, Groundwater level, Coastal plains, *Maryland, Magothy aquifer, Cone of depression.

The map is based on the differences between two sets of water-level measurements made in 65 observation wells. One set was made in 1977, a relatively dry year, and the other set was made in 1980, another relatively dry year. The map shows that the potentiometric surface was higher in 1980, by as much as 9 feet, than it was in 1977, in a band a few miles wide near the outcrop and subcrop areas of the aquifer in northern Prince Georges County and central Anne Arundel County. In the remainder of the map area, the 1980 potentiometric surface was lower than it had been in 1977, with declines as great as 20 feet measured in well fields at Waldorf and Chalk Point. The network of observation wells was developed and is operated and maintained as part of the cooperative program between the U.S. Geological Survey and agencies of the Maryland Department of Natural Resources. (USGS)

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER, SOUTHWEST FLORIDA WATER MANAGEMENT DISTRICT, SEPTEMBER 1981,
Geological Survey, Tampa, FL. Water Resources Div.
D. K. Yobbi, and G. R. Schiner.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $2.50 in paper copy, $.50 in microfiche. Geological Survey Open-File Report 82-101, 1981. 1 Sheet.

Descriptors: *Potentiometric level, *Groundwater, *Maps, *Aquifers, Water table, Wells, Water level fluctuations, Geohydrology, *Florida, Southwest Florida, Southwest Florida Water Management District.

A September 1981 potentiometric-surface map of the Southwest Florida Water Management District depicts the annual high water-level period. Water levels in most wells measured in September 1981 are equal to or higher than in May 1981. Levels averaged about 26 feet higher in the southern part of the area and 5 feet in the north. In the agricultural sections of southern Hillsborough, Hardee, southwestern Polk, northwestern De Soto, and Manatee Counties, water levels increased 10 to 46 feet. From September 1980 to September 1981, water levels ranged from a decrease of 11 feet in Citrus County to an increase of 9 feet in southern Hillsborough County. (USGS)

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER IN THE ST. JOHNS RIVER WATER MANAGEMENT DISTRICT AND VICINITY, FLORIDA, SEPTEMBER 1981,
Geological Survey, Tallahassee, FL. Water Resources Div.
G. R. Schiner, and E. C. Hayes.
Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $3.50 in paper copy, $.50 in microfiche. Geological Survey Open-File Report 82-118, 1981. 1 Sheet.

Descriptors: *Potentiometric level, *Groundwater, *Maps, *Aquifers, Water table, Wells, Water level fluctuations, Geohydrology, *Florida, East-central Florida, St. Johns River Water Management District.

This map presents the potentiometric surface of the Floridan acquifer in the St. Johns River Water Management District and vicinity for September 1981. The Floridan acquifer is the principal source of potable water in the area. Water-level measurements were made on approximately 1,000 wells and on several springs. The potentiometric surface is shown mostly by 5-foot contour intervals. In the Fernandina Beach area 20- and 40-foot intervals are used to show a deep cone of depression. The potentiometric surface ranged from 134 feet above NGVD (National Geodetic Vertical Datum of 1929) in Polk County to 90 feet below NGVD in Nassau County. Record low water levels for September were recorded in many counties due to lack of rainfall. September 1981 levels were as much as 10 feet and commonly 2 to 3 feet lower than the below normal September 1980 levels. Water levels rose from September 1980 levels on the coastline at St. Augustine and from Flagler Beach south to New Smyrna Beach. (USGS)
W82-05849

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER IN CENTRAL SUMTER COUNTY, FLORIDA, SEPTEMBER 1981,
Geological Survey, Orlando, FL. Water Resources Div.
L. A. Bradner.
Available from the OFFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $2.50 in paper copy, $.50 in microfiche. Geological Survey Open-File Report 82-259, 1982. 1 Sheet.

Descriptors: *Potentiometric level, *Groundwater, *Maps, *Aquifers, Water table, Wells, Water level fluctuations, Geohydrology, *Florida, Sumter County, Floridan aquifer.

This map presents the potentiometric surface of the Floridan aquifer in central Sumter County, Florida, for September 1981. The Floridan aquifer is the principal source of potable water in the area. The focus of the map is the potentiometric surface in the Jumper Creek Canal area for the high water-level period. Water-level measurements were made on approximately 60 wells. The potentiometric surface ranged in altitude from more than 85 feet in the southeast part of the county to less than 35 feet northwest of Lake Panasoffkee in the west-central area. (USGS)

RECONSTRUCTION OF THE NORTHERN DONETS-DONBAS CANAL,
G. P. Zhuk, and V. A. Osadchuk.
Hydrotechnical construction, No 8, p 765-772, August, 1980. 3 Fig, 3 Tab, 5 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 5-9, August, 1980.

Descriptors: *Water conveyance, *Conveyance structures, Water transport, Canal construction, Construction methods, Expansion, *USSR, *Donbas Canal, Water demand.

One of the major factors determining the further development of industrial centers in the Soviet Union is the availability of adequate water supplies. In many cases, an effort is made to improve the water supply by increasing the capacity of the main pipelines without reconstructing the existing carrier canals. The Northern Donets-Donbas canal, which began operations in 1958, has undergone two major reconsructions without ever being shut down. The canal is the main source of drinking and industrial water supply for the majority of the industrial regions of the Donbas. The main

canal has a total length of 131.6 kilometers, of which 101.4 kilometers are open channel. Sag pipes, pressure pipes for pumping stations, and closed stretches of the canal comprise the remaining length. The first reconstruction of the canal, accomplished between 1966 and 1972, increased the discharge from the canal from 25 cubic meters per second to 32 cubic meters per second. The second reconstruction, carried out between 1973 and 1979, increased this discharge to 43 cubic meters per second. Activities conducted during each of the reconstructions are discussed. It is concluded that stagewise reconstruction of open canals can be accomplished under conditions of uninterrupted operation and that reconstruction of the structures and channel of existing canals provides an economical and expedient means of increasing water supplies. THE SEARCH FOR RESERVOIR SITES IN AN URBAN ENVIRONMENT,
Thames Water Authority, London (England).
C. S. Sinnott, and M. H. Davies.
Journal of Hydrology, Vol 51, No 1-4, p 219-230, May, 1981. 1 Fig, 4 Tab, 3 Ref.

Descriptors: *Reservoir sites, *Urban areas, *Site selection, Reservoir siting, Cost analysis, Dams, Economic aspects, Environmental effects, London, *Great Britain, Storage reservoirs, Water supply.

Increases in the demand for water have traditionally led to the construction of larger and larger reservoirs, both increasing the environmental impact and necessitating the location of these reservoirs at greater distances from the center of demand. The alternative to the development of these large and remote storage reservoirs to meet the needs of urban areas is to set aside engineering and size considerations and identify sites which are primarily acceptable in terms of land use and environmental value. The Thames Water Authority, which is responsible for the catchments of the Thames and Lee rivers and for the London area in Great Britain, initiated a systematic survey to identify all possible reservoir sites within the area. Plans of each site were used to measure the dam length, maximum depth of the dam, and surface area for each dammed site and the surface area and perimeter of embankment for each impounded site. Estimates of the total costs of constructing the reservoir and the cost per unit volume of water stored were calculated for each site. The geological suitability of each site was evaluated to determine the potential need for lining. Each site was visited to check its suitability and to identify current usage and recent developments in the area. In order to quantify environmental effects, suitability grades were assigned on the basis of the amount of land affected, the quality of the land, the quality of the surrounding environment, and the remoteness from water. Finally, details of the suitability assessment, unit costs, and other data relating to each site were evaluated to classify the site as possible, doubtful, or unsuitable. A discounted cost analysis showed that the use of smaller sites meeting environmental constraints need not lead to financial penalties over the use of large sites. (Carroll-FRC)

THE RIVIERSONDEREND-BERG RIVER-JONKERSHOEK PROJECT MOST OUTSTANDING CIVIL ENGINEERING ACHIEVEMENT OF 1980.
Civil Engineering in South Africa, Vol 23, No 11, p 517, 519, 520, November, 1981. 6 Fig.

Descriptors: *Water supply development, *Dams, Civil engineering, *South Africa, Construction, Tunnels, Rivers.

The Riversonderend-Berg River-Jonkershoek Project was designed to collect surplus winter run-off of the upper reaches of the Berg, Dwars and Eerste Rivers and their tributaries, and divert all this water to the neighboring South Western Cape where conventional sources have fallen short of water demand, especially during the summer months. The Theewaterskloff Dam in the Riviersonderend was chosen for storage. The dam receives water directly from the Riviersonderend catchment and via the tunnel system from the Berg catchment. Theewaterskloof is a conventional earth dam with a 38 meter high dam wall and a 680 meter crest length. A spillway, capable of handling a probable maximum flood of 394 cubic meters/second, is of the side channel type and the chute ends in a stilling basin. The tunnel construction was the most challenging part of the project. The largest problem occurred when the Franschhoek tunnel penetrated through the granite at a point where a major fault coincided with the granite/sandstone contact. Environmental considerations played an important role in the planning and execution of the project. Much research was done to combat the potential problem of windblown sand conditions at the Theewaterskloff Dam. During winter months water will be diverted under force of gravity from the 1 million cubic meter capacity Klein Drakenstein Dam in the Elands River to Theewaterskloof via the proposed pipeline and the Dasbos and Granschhoek tunnels. In summer water from Theewaterskloof will flow back through the tunnel system and the pipeline as part of the supply to the Berg River area from Dasbos. (Baker-FRC)

BOTTOM-ENTRY LARGE-DIAMETER WELLS,
Food and Agricultural Organization of the United Nations, Rome (Italy). Land and Water Development Div.
R. G. Thomas.
Ground Water, Vol 20, No 1, p 96-98, 1982. 1 Fig, 1 Tab, 2 Ref.

Descriptors: *Deep wells, *Open wells, *Partially penetrating wells, *Cost analysis, *Well hydraulics, Wells, Screened wells, Well screens, Screens, Laminar flow, Mathematical equations, Water storage, Drawdown, Aquifer characteristics.

In areas where there are highly permeable gravel aquifers of relatively shallow depth, the bottom entry large-diameter well should be considered as an alternative to drilled and screened wells. In constructing a large-diameter well, a concrete or other casing is sunk as digging proceeds. When the water table is reached, a grab bucket device is usually needed for dewatering to continue digging. In low permeable rocks, large-diameter wells provide storage of water. For a 75% penetrating well, discharge increases roughly by 70% for each doubling of the radius. Drawdown outside the casing is not very great, making these wells a poor choice for drainage purposes. Nonlaminar flow conditions were examined using the Forchheimer equation. To prevent sand filling, a natural gravel pack is allowed to form, or backfilling with coarser clean gravel is employed. The capital costs for large-diameter well operation will depend on the well location. The large diameter, bottom entry well can use a centrifugal pump rather than a turbine pump which is also a savings in energy costs. (Geiger-FRC)
W82-04919

CAVITY WELL,
Food and Agricultural Organization of the United Nations, Rome (Italy). Land and Water Development Div.
R. G. Thomas.
Ground Water, Vol 20, No 1, p 94-95, 1982. 1 Tab, 5 Ref.

Descriptors: *Well hydraulics, *Irrigation wells, *Well casing, *Fully penetrating wells, *Pump wells, Wells, Groundwater mining, Alluvial plains, Test wells, Well yield, Deep wells, Drawdown, Economic aspects.

Cavity wells have been used in India's Gangetic alluvial plain for the past 15 years. The alluvium sand stringers are often overlain with fine silt clays with reasonably developed soil profiles, root casts, and Kankars (calcium carbonate rock fragments). The cavity well is constructed with a tripod and bailer bit. When the water table is reached, blank casing is installed and drilling continues. The blank casing is then pulled back about 0.5 m into the clay layer and a centrifugal test pump is installed. The well is pumped at a low rate until the sand no longer comes out. The pumping rate is then increased in small stages until the discharge is somewhat greater than what the farmer will need. Such wells usually last at least 5 years and may be replaced with relative ease. In a comparative test, a fully penetrating well gave a discharge of 41.4 cu m/h while the cavity well discharged only 36.7 cu m/h. The cavity well seems to be economically feasible for this section of India. More research is needed into the conditions of stability for the construction of deeper wells. (Geiger-FRC)

During the floods of August, 1978, severe damage was sustained by the Palagnedra reservoir and other installations of the Verbano hydroelectric scheme in Ticino, Switzerland. Early on in the event the diversion tunnel was progressively opened. Later between 4 and 6 p.m. it was gradually closed, in response to a request by the police, in the hope of delaying the flooding of a camp ground about 10 km downstream from the dam. The flood had the following consequences: overtopping of the dam occurred along its full length, resulting in an erosion breech 30 meters deep and 25 meters wide in the morainic material supporting the diaphragm: about 25,000 cubic meters of wooden debris and logs of all dimensions from forests in the upper parts of the catchment found their way into the reservoir; about 1,800,000 cubic meters of sand and gravel from various centers of erosion entered the reservoir; the part of the reservoir upstream of the intermediate dam was completely filled up, so that the sill at the inlet of the diversion tunnel was covered by sand and logs 12 to 14 meters deep; the gauging station of the Melezza, near Camedo just upstream of the reservoir was destroyed at 7 pm; and the grating of the water intake was partly destroyed, blocking the bypass tunnel. The storm itself was exceptional both in its large area of high precipitation and in an unusual general meteorological situation. A physical model was constructed to better understand the behavior of the mass of wood carried by the bore in the canyon and to the spillway. Remedial work and efforts to improve forecasting are underway. The major lesson learned concerns the design of the spillway. (Baker-FRC)

HYDRAULIC CALCULATIONS OF STABLE UNLINED CANALS BY THE VERTICAL VELOCITY DISTRIBUTION METHOD,
G. P. Skrebkov.
Hydrotechnical Construction, Vol 15, No 6, p 346-350, June, 1981. 3 fig, 10 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 25-28, June, 1981.

Descriptors: *Canal design, *Flow velocity, *Channel erosion, Channel morphology, *Design criteria, Velocity distribution, Hydraulic design, Erosion, Stable channels, *Sediment transport, Soil mechanics, Siberia.

The permissible velocity method of designing unlined canals, unsuitable for very large canals used for runoff diversion of northern and Siberian rivers, was modified by considering the hydraulic stability of the channel on any stretch. The mean velocity of flow was replaced with the averaged velocity on a vertical. The permissible velocity of the flow was replaced with the permissible velocity of the same vertical. This allowed evaluation of the stability of channels composed of different soils and the selection of a hydraulically stable cross section. The permissible velocity distribution was plotted using equations for the permissible velocity for noncohesive soil on a horizontal bed with Lane's correction to account for the decrease in stability of the soil particles on the slope. A sample problem, calculation of a hydraulically stable canal for discharging 1000 cu m per sec in sand, illustrated the method. An approximate depth of 16-18 m and a parabolic shape was first estimated. Testing a 17 m depth in the equations showed that the cross section obtained would produce and erodible channel. Consideration of the sand dune formation produced a final channel of 6.5 m deep, 170 m surface width, 3700 sq m cross sectional area, mean velocity 0.27 m per sec, and velocity on the channel axis, 0.286 m per sec. This approached the shape of a natural river channel. (Cassar-FRC)

CONTROLLING THE QUALITY OF COMPACTION OF EARTH FILL IN THE CONSTRUCTION OF HIGH DAMS,
S. V. Bortkevich, V. I. Vutsel', A. G. Chernilov, and N. F. Roiko.
Hydrotechnical construction, Vol 15, No 5, p 263-269, May, 1981. 4 Fig, 2 Tab, 10 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 5, p 9-12, May, 1981.

Descriptors: *Compaction, *Quality control, *Dam construction, Soil mechanics, Earth dams, Soil compaction, Soil physical properties, Nurek Dam, Density, Sampling, Soil density.

A method for quality control of compaction during earth dam construction was developed and tested during building of the Nurek Dam. Quality of compaction depended on elative density. Monolith samples weighing 3-5 kg were removed from the compacted area. Samples of fines from the same area were collected simultaneously. After weighing to ensure that samples contained no cracks, the content of the fines in the monolith and the monolith dry density were determined. the placement density of the fines and of the soil as a whole were determined by equations. This method required samples of 2-3 liters compared with up to 1000 liters for the pit sampling method. Maximum error was + or - 20 kg per cu m. (Cassar-FRC)

SHAFT SPILLWAYS COMBINED WITH A WATER INTAKE,
A. N. Aliferov.
Hydrotechnical Construction, Vol 15, No 5, p 311-314, May, 1981. 3 fig, 6 ef. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 5, p 53-55, May, 1981.

Descriptors: *Spillways, *Intakes, *Dam design, Hydraulic structures, Rivers, Hydroelectric plants.

A combination spillway and intake was designed to reduce costs and save space at hydrostations on mountain rivers. These structures discharge flood water, take in water from the reservoir, divert water temporarily, and empty the reservoir to flush sediment. A typical project has a horizontal tunnel, intake tower, inclined shaft, and a connecting structure. The spillway shaft is inclined at an angle of 60 degrees to the tunnel, providing a free-flow hydraulic regime over the length of the spillway passage. Extensive aeration is produced. A ski jump bucket is used to connect the flow from spillway to river. Large, strong rocks are placed at the point of impact to prevent scouring of the river bed. (Cassar-FRC)

STRESS-STRAIN STATE OF AN ARCH DAM BASED ON DATA OF LONG-TERM ON-SITE OBSERVATIONS,
I. F. Blinov, E. M. Mirzak, and Y. P. Shaikan.
Hydrotechnical Construction, Vol 15, No 6, p 360-365, June, 1981. 3 Fig, 3 Tab, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 34-38, June, 1981.

Descriptors: *Stress analysis, *Dam stability, *Concrete testing, Strain measurements, Hydroelectric plants, Temperature effects, Design criteria, *Arch dams, Safety, Dam foundations, Reservoirs.

Stress-strain monitoring equipment consisting of 885 transducers and meters was installed in a double arch dam 70 m high and 285 m long to study deformations and temperature changes during filling, October 1971 to 1980. Temperatures were governed by seasonal temperatures, structural features, and orientation toward the sun. The temperature difference between the surfce layer of the rock foundations and the concrete stabilized at 4 C in October 1971 when the water level reached 22 m. Deformations of intersectionsl joints in the dam were described. Most separations were less than 0.2 mm. After regrouting several joints which had opened to 2.1-4.3 mm, no further openings were observed in these sections. There was some disturbance of the joint between the concrete and the foundation during construction. After the reservoir was filled to 52 m, the maximum opening decreased to 0.05-0.5 mm. Vertical and horizontal movements by the dam varied within + or - 2.0 mm. Stresses observed were within those assumed in design. (Cassar-FRC)

DESIGN OF THE COMPOSITION OF TRANSITION LAYERS OF ASPHALTIC CONCRETE MEMBRANES IN EARTH DAMS,
Y. N. Kasatkin.
Hydrotechnical Construction, Vol 15, No 6, p 357-360, June, 1981. 3 Fig, 1 Tab, 2 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, 32-34, June, 1981.

Descriptors: *Asphalt concrete, *Dam design, *Soil porosity, Concretes, *Earth dams, Soil mechanics, Pores, Transition zone, Rocks, Soil compaction, Compaction.

Equations were developed to describe the penetration of asphaltic concrete into soil pores. This is important in design of earth dams containing asphaltic concrete membranes. Use of the equations was illustrated in a sample problem in which available rock at a construction site was evaluated for suitability as a component of the transition layer of a membrane being made of plastic coarse-grained asphaltic concrete. DAMMING OF THE KARA-BOGAZ-GOL STRAIT WITHOUT SIDE DIVERSION OF THE FLOW,
P. K. Osokin, D. L. Melamut, N. K. Golubev, and F. G. Zagirov.
Hydrotechnical Construction, Vol 15, No 6, p 324-328, June, 1981. 6 Tab, 1 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 11-14, June, 1981.

Descriptors: *Dam construction, *Hydraulic fill, Cofferdams, Water level, *Kara-Bogaz-Gol Gulf, *Caspian Sea, Engineering.

Damming of the 200-250 m wide, 7 km long strait between the Caspian Sea and the Kara-Bogaz-Gol gulf was accomplished without side diversion of the flow. There was a 2 m high waterfall in an erodible rock channel between the two water bodies, which had the potential for a breakthrough of water from the sea into the gulf, a natural evaporator. Although the hydrological conditions during the scheduled construction period, fall-winter 1979-1980, were more severe than were considered in planning, the project proceeded. The gap was narrowed by hydraulic filling with sand to the point where the flow eroded the added material. At this stage of 70 m opening remained. Local stone and cement-sand cubes were used to fill the space until a 23 m wide gap remained. The final stage of closure was the most strenuous. This was accomplished by first protecting the left bank and end of the cofferdam with old steel frameworks filled with scrap stone matrial. Sand-cement cubes, cabled together, were pushed into the gap and empty space filled with stone. An underwater still 40 m downstream helped to decreased the difference in water levels between the gulf and the sea to 1.21 m drom the original 2.03 m. (Cassar-FRC)

Potential dam break model users are guided in selection and application of available models. A high-hazard category test dam example provided a means for comparing and evaluating different approaches to dam break analysis. A review of dam failure model literature showed that few computerized models were ready for immediate general application. The National Weather Service (NWS) DAMBRK Model, the HEC-1 Dam Safety Version Model, and the Soil Conservation Service (SCS) Simplified Dam Break Procedure were chosen for testing and evaluation. Additionally, Keulegan's classic instantaneous dam-break equations were used to estimate and compare instantaneous peak flow at the failed test dam. These four approaches were applied to a 36-foot-high homogeneous earthen embankment for a design PMF inflow hydrograph. The downstream test reach extended one-half mile below the test dam. The computerized NWS and HEC-1 models are capable of handling a variety of complex dam breach problems. The hand-worked SCS and Classic methods provided a quick analysis of simple types of dam break problems. A self-explanatory comparative evaluation of the capabilities and costs of

different dam break models is presented to guide model users in choosing the appropriate models for specific dam break situations and for given resources.

SAFETY ANALYSIS OF HIGH HAZARD DETERIORATING CONCRETE GRAVITY DAM-RESERVOIR SYSTEMS INCLUDING CORRECTIVE MEASURE - EARTHQUAKE AND DYNAMIC STUDY,
Delaware Univ., Newark. Dept. of Civil Engineering.
C. Y. Yang, V. Chiarito, and P. Dressel.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224718, Price codes: A06 in paper copy, A01 in microfiche. Report, October 1981. 9 p, 35 Fig, 9 Tab, 43 Ref, 4 Append. OWRT A-047-DEL(4), 14-34-0001-1108.

Descriptors: *Concrete dams, *Safety, *Earthquake engineering, *Probabilistic process, *Gravity dams, *Reservoir design, *Dynamic programming, Dams, Construction, Earthquakes, Engineering, Assessments, Mathematical studies, Reservoir construction, Dam construction, Systems analysis, Durability, Hazards, Dam design, Design criteria.

Research was carried out to analyze the safety of high-hazard deteriorating concrete gravity dam-reservoir systems against earthquakes, using the Delaware Hoopes Dam as a model. Due to the uncertainty in earthquake occurance and magnitude, a probabilistic approach to the dam-reservoir-earthquake problem was sought. Design and analysis based on probability concepts were worked out in detail for the Hoopes Dam. The result of this study revealed a lower design earthquake than that currently used by engineers. In addition, the effectiveness of the post tension strengthening techniques currently used by engineers was studied using a crude dynamic analysis, with the finding that the strengthening technique is highly effective in resisting earthquake shocks, provided that the cable system is correctly designed and constructed. FROGMEN'S SUBTERRANEAN SWIM SITES SOURCE,
World Water, Vol 5, No 2, p 17-18, February, 1982. 4 Fig.

Descriptors: *Exploration, *Excavation, *Water resources development, Water demand, Water supply, Drinking water, Groundwater Aquifers, Financial aspects, Constsruction, France, Karst.

In May of 1973 divers entered the 35 m-diameter pond of Le Lez and penetrated 520 meters upstream to find the top of a seemingly bottomless pit. Based on their efforts, engineers constructed a new subterranean intake structure which will yield some 2 cubic meters/second for future use in the city of Montpellier, France and the surrounding areas. A pumping station was built 30 meters below the surface and immediately above this 'bottomless pit'. A 230 meter long, 1.8 meter diameter tunnel was cut, using liquid oxygen to freeze the ground. The tunnel will carry water from the underground pumphouse to the intake of the aqueduct of Le Lez spring. The underground pumphouse was also excavated using the liquid oxygen method, with a concrete lining poured behind shuttering for the vaulted roof in advance of excavating the main chamber. Three pumps will lift water through shafts to the newly driven supply tunnel. The construction project is now halfway to completion. Water consumption in the city of Montpellier has doubled over the past 20 years, making some basic improvement in supply a matter of urgent necessity. The groundwater has excellent quality and will be cheaper to use than surface water, which would need significant treatment. (Baker-FRC)

SELECTING THE OPTIMUM CROSS-SECTION OF A CONCRETE GRAVITY DAM,
Ministry of Energy, Sofia (Bulgaria).
S. Iliev, and L. Kalchev.
International Water Power and Dam Construction, Vol 33, No 12, p 23-27, December, 1981. 2 Fig, 3 Tab, 4 Ref.

Descriptors: *Gravity dams, *Dam design, *Concrete dams, Dam construction, Computer programs, Design criteria, Mathematical equations.

The natural terrain, concrete qualities, and underground outline of a concrete gravity dam are characterized by a number of factors which directly affect the choice of its cross-section. A computer program has been developed which used 11 inputs to formulate an optimum cross-section of a dam which can then be subjected to comprehensive static investigations. The inputs include the design factor of friction between concrete and rock at the baseline, the design stress of adhesion between concrete and rock at the baseline, characteristics of the construction soil, density of the concrete, density of the water, the design factor of safety against sliding, the uplift factor at the upstream side, the uplift factor at the drainage curtain, the uplift factor at the downstream side, the ratio between the distance from the upstream edge of the line of intersection of the baseline with the drainage curtain and the length of the baseline, the design ratio between the vertical and main stress, and the dam height at the downstream edge of the baseline. The main objective of this method is to provide a rapid and adequate guide to an optimum solution and, by selected combinations of the factors influencing a dam's cross-section, to permit the best assessment of their importance. The program provides a number of solutions from which the engineer may choose the most appropriate. Additional sets of solutions can be obtained by altering the inputs. In addition, this proposed method of deriving a generalized criterion for choosing a cross-section can include factors such as compression caused by sediments or seismic forces without changing the structure of the equation expressing the generalized criterion. SAFETY OF DAMS JUDGED FROM FAILURES,
COBA International Consultants, Lisbon (Portugal).
J. L. Serafim.
International Water Power and Dam Construction, Vol 33, No 12, p 32-35, December, 1981. 3 Fig, 1 Tab, 13 Ref.

Descriptors: *Dam failure, *History, Dams, Safety, Dam construction, Dam stability, Prediction, Mathematical studies, Disasters, Probabilistic process, Statistical studies.

Recent statistical studies based on the historical records of disasters and incidents associated with large dams have led to the development of failure probability predictions applied to dams of any kind built. It is suggested that such an assessment is misleading and erroneous, since the percentage of failures is currently falling and careful design, construction, and instrumentation is likely to reduce the failure rate even further. Review of the available data on failures of dams more than 15 meters high since 1796 which haae been registered at Electricite de France through 1979 shows that there are many qualifying conditions. Without considerration of such qualifying characteristics as height, type of dam and construction standards, age, number of inspections, maintenance conditions, and instrument monitoring, simple statistical numbers of disasters per year are meaningless. Review of the failures of 136 dams throughout the world showed that the large majority (90) occurred in dams between 15 and 30 meters high and that 80 of the failures involved earth dams. Dams in remote areas are more prone to failure. In addition, dams are much more vulnerable during and immediately after construction than after they become operative. The most frequent failures occur during the first complete filling of the reservoir. It is suggested that perhaps 70% of all dam failures could be prevented if first fillings of new dams were carefully controlled, supervised, and monitored with instruments and if all old dams were the object of careful inspection and calculation. COMPARISON OF ISOSTATIC AND HYPERSTATIC PENSTOCKS AT SANTA ISABEL, BOLIVIA,
Montreal Engineering Co. Ltd. (Quebec).
J. L. Gordon, W. Bolliger, and J. S. Cary.
Canadian Journal of Civil Engineering, Vol 9, No 1, p 1-12, 1982. 12 Fig, 7 Tab, 4 Ref.

Descriptors: *Penstocks, *Design criteria, Construction, Dams, Water resources development, Planning, Santa Isabel, Boliva.

In 1973 work was completed on the construction of the Santa Isabel hydroproject in central Bolivia. The project includes a penstock, with the lower half comprising an unusual hyperstatic design with no expansion joints and anchors at alternate bends. The penstock was designed for a static head of 864 meters plus 15% waterhammer. It burst when filled with water on March 16, 1973 at a head of 735 meters. An improper weld at an unsupported bend in the hyperstatic section of the penstock was blaimed for this failure. In March 1981 consturction of a second parallel penstock was completed. Use was made of an isostatic upper half and hyperstatic lower half penstock at Santa Isabel; this was justified on the grounds of having to parallel an existing penstock of similar design. It became evident after work had been completed that an all-isostatic design would have been very close in cost to the combined isostatic-hyperstatic design. There was very little difference in the weight of steel between an isostatic penstock having expansion joints between anchors and a hyperstatic penstock where every alternate anchor is eliminated and the free bend allowed to move with thermal expansion and contraction. There is a substantial reduction in anchor block concrete in a hyperstatic penstock, compared with an isostatic penstock. There is also a substantial increase in pier concrete in a hyperstatic penstock compared with an isostatic one. Finally, there was very little net difference in total anchor and pier concrete between the two types of penstock. Notwithstanding this financial consideration, it was necessary at Santa Isabel to use the hyperstatic penstock design to avoid an unstable area. It is recommended that hyperstatic penstocks be used only when the geological or topographical conditions do not favor use of an isostatic design penstock. (Baker-FRC)

UPLIFT PRESSURE OF WATER ON THE BASE OF HYDRAULIC STRUCTURES IN LIMIT DESIGN STATES (DISCUSSION OF CONSTRUCTION SPECIFICATIONS),
R. N. Petrashen.
Hydrotechnical Construction, Vol 15, No 7, p 427-431, 1981. 1 Fig, 7 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 7, p 33-35, July, 1981.

Descriptors: *Water pressure, *Dam foundations, Rock mechanics, Hydraulic structure, Uplift pressure, Pressure distribution, Dam design, Design criteria, Limiting factors, Dam failure, Seepage.

The equation for calculating total uplift pressure of water on the base of a structure may be expressed as $Q = a2qF$, where F = the total area of the base of the structure, f = the area of the close contacts where seepage water cannot penetrate, and $a2$ = a coefficient equal to $(1 - f/F)$. Current design practices call for calculations with respect to limit states (the condition existing just before failure). However, previous theoretical and experimental investigations of uplift did not indicate the state under investigation, nor did they account for changes in density and loads in fracture or shear zones. The coefficient a2 has been arbitrarily as-

signed values from 0.5 to 1. Calculations how that the coefficient a2 should be assumed equal to 1 in the limit state and in elastic states in the operating stages for all materials with relatively large values of water permeability and sufficiently long action of the head. It is possible that a2 can have a value of less than unity in the elastic state for massive rigid materials under moderate stresses. The exact values must be obtained experimentally. (Cassar-FRC)

SELECTION OF TEMPORARY DIVERSION TUNNELS AND TUNNEL SCHEMES FOR DISCHARGE OF WATER,
E. I. Karabaev.
Hydrotechnical Construction, Vol 15, No 8, p 476-488, 1981. 5 Fig, 14 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 30-38, August, 1981.

Descriptors: *Diversion structures, *Tunnels, *Hydroelectric plants, Construction, Rivers, Dam construction, Flow regulation, Hydraulic structures, Optimization, Design criteria.

Diversion tunnels in 38 Soviet and 105 foreign hydrostations are statistically analyzed. All temporary and combined tunnels can be classified into four groups: uncombined diversion tunnel spillways, combined diversion-service tunnel spillways, diversion-service tunnel structures combining functions with the turbine tunnels, and diversion-service tunnel structures partially combined with the headrace and tailrace tunnels. Types of diversion tunnels used are principally determined by the following parameters: width and shape of river canyons at the hydrostation site, character of the runoff hydrograph and design discharges, type and height of the dam, location and type of the power station, presence of permanent service tunnel structures as part of the hydrostation, and construction characteristics. A list of 5 basic principles for selecting tunnel schemes and parameters of diversion tunnels for specific cases is presented. To minimize cost the following basic principles apply: stage-by-stage examination of water diversion at the site, determination of the permanent set of components of the cost and structures of the system providing diversion at each state under the specific conditions of the hydrostation, calculation of the cost related to diversion under the given conditions of the investigated stage, and performance of the comparative technicoeconomic calculations of the diversion system for each alternative of tunnel parameters. PROSPECTIVE ENGINEERING DESIGNS FOR UNDERGROUND HYDRAULIC STRUCTURES,
V. F. Ilyushin.
Hydrotechnical Construction, Vol 15, No 8, p 439-447, 1981. 8 Fig. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 9-14, August, 1981.

Descriptors: *Hydraulic structures, *Tunnel construction, *Underground structures, Spillways, Water conveyance, Intakes, Tunnel lining, Conduits, Grouting, Design criteria.

New engineering designs developed and used in construction of underground structures of the high-head Central Asian hydrostations are described. These stations operate under conditions of high water pressures and high flow velocities. Intake designs include automatic flow proportioning between different sections of a submerged intake to handle trash clogging, a surface intake-spillway, and a multilevel inlet adjustable to different degrees of siltation. The underground spillway transition section of the Papan Reservoir splits the flow to preclude overpressurization of the outlet tunnel, reduce hydrodynamic loads on the bottom and walls of the transition chamber. The Nurek hydrostation transition section of the service spillway contains a quick-knockdown concrete plug for switching channels. For pressure conduits, corrugated steel linings equipped with circular stiffeners with blind notches opposite the corrugations are proposed to improve the contact with surrounding rock. Steel interblock closures in tunnel spillways are being replaced with polymer concrete or other wear and cavitation resistant material. Drainage to protect tunnel linings can be accomplished by leaving a small layer of ungrouted rock between the tunnel lining and the grouted layer. Water entering this permeable layer is discharged through a drainage system. (Cassar-FRC)

THE EXPANSION OF TWO BOLIVIAN PLANTS,
Empresa Nacional de Electricidad, Cochabamba (Bolivia).
M. Zenteno, A. W. Williams, and J. L. Gordon.
International Water Power and Dam Construction, Vol 34, No 2, p 26-28, 29-31, February, 1982. 5 Fig, 3 Ref.

Descriptors: *Powerplants, *Construction, Construction materials, Design criteria, Dams, Reservoirs, Bolivia.

The central Bolivian electric system had two powerplants with a total installed capacity of 180 MW, the Corani and Santa Isabel hydroplants, regulated by the Corani storage reservoir. Construction of the first phase of the Corani development was completed in 1967 with the commissioning of two 15 MVA units. Flood relief is provided by a masonry weir spillway. The 659 meter long penstock, of conventional design, has expansion joints between the anchor blocks. The penstock varies in diameter from 1 meter at the upper end down to 0.9 meters at the lower end, where it bifurcates to the two units. The Corani powerhouse comprises a concrete slab with footings for a concrete column and beam superstructure and a steel truss supporting an aluminum roof, all founded on a dense clay soil containing large boulders. A re-regulating reservoir having a nominal storage of 100,000 cubic meters has been built between Corani tailrace and the Santa Isabel intake. The reservoir will be used to even out the usage and demand for water between the two powerplants and to store flash-flood flows from the Vinto river intakes. During construction of the Santa Isabel tunnel, an access adit was built from the Vinto river valley, which is now used as a water passage to direct the diverted water from the east and west branches of the Vinto river into the Santa Isabel tunnel. The Santa Isabel penstock with a length of just under 2.8 km constituted a major portion of the work required to expand the development. (Baker-FRC)

THE AGUS II SCHEME IN THE PHILIPPINES,
National Power Corp., Manila (Philippines).
S. J. de Jesus, and R. P. Clark.
International Water Power and Dam Construction, Vol 34, No 2, p 17-23, February, 1982. 8 Fig.

Descriptors: *Dams, *Construction, Environmental effects, Philippines, Agus River, Hydroelectric plants, Powerplants, Mindanao.

Lake Lanao has a surface area of 350 square kilometers and a total drainage area of 1680 km. The Agus river is the single outlet of the lake. A cascade of seven dams has been planned, with Lake Lanao serving as a natural regulating pond. The optimized operation of Lake Lanao based on maximized total energy output in the Agus project chain resulted in a capacity of 944 MW. The site of Agus II is 6 km downstream of Lake Lanao, with elevations ranging from 650 at the dam to 420 at the tailrace channel. The terrain varies from gently rolling to steep. The deeply weathered lava flows render the foundation unsuitable for a concrete dam, so that only an earth dam was feasible. The dam constructed is a homogeneous earth dam with a sloping filter drain leading into a downstream horizontal blanket. The spillway consists of two bays with bottom radial gates 11 m wide and 7.5 m high. The contract for the construction of the powerplant was awarded in December of 1974. Right-of-way problems prevented the immediate acquisition of the land for the dam and the main structures. Excavation of the powerhouse began in June 1975. Excavation of the spillway, intake structure and approach canal started in January 1976. Impounding of the reservoir began in April 1979, in stages as permitted by the advancement of the approach canal lining. (Baker-FRC)

AERATION AT HIGH VELOCITY FLOWS,
Parana Univ., Curitiba (Brazil).
N. L. de S. Pinto, S. H. Neidert, and J. J. Ota.
International Water Power and Dam Construction, Vol 34, No 2, p 34-38, February, 1982. 12 Fig.

Descriptors: *Entrainment, *Spillways, Design criteria, Model studies, High flow, Flow velocity, Cavitation, Aeration, Brazil, Dams, Foz do Areia Dam, Construction.

This article deals essentially with the phenomenon of air entrainment during high velocity flows down spillway chutes. Based on a general analysis of the air entrainment mechanism and of data from prototype and laboratory tests, an analytical treatment of the problem is developed, setting a basis for predicting the performance of aeration devices from hydraulic model studies. An aeration system during the design stage should be considered in the following light: at what velocity should first aeration be provided, what is the volume of air entrained at the aeration, and what is the spacing between aerators to maintain a given protection level. Tests were performed at the Foz do Areia spillway, on the Iguacu river in Brazil. During the initial phase of spillway operation, measurements of air flow entrained at each aerator for different water discharges from 500 to 3300 cubic meters/second were made. The water discharges were determined from spillway rating curves obtained in a 1:100 cale hydraulic model. Air discharges were calculated from pressures measured at the walls of the aeration towers, used as Venturi meters. Pressure distribution was also measured under the jet along the step wall of the aerator. (Baker-FRC)

CABLEGATION: I. CABLE CONTROLLED PLUGS IN PERFORATED SUPPLY PIPES FOR AUTOMATIC FURROW IRRIGATION,
Science and Education Administration, Kimberly, ID.
W. D. Kemper, W. H. Heinemann, D. C. Kincaid, and R. V. Worstell.
Transactions of the ASAE, Vol 24, No 6, p 1526-1532, 1981. 12 Fig, 1 Tab, 4 Ref.

Descriptors: *Irrigation engineering, *Plug flow, Pipe flow, Pipes, Cablegation, Design criteria.

To encourage farmers to reconsider surface irrigation, systems are needed that will provide uniformity of water distribution, have low initial and maintenance costs, minimize labor input, and do not hinder field operations. Such a system is described. A single pipe line serves both the transmission and distribution functions at the head of a furrowirrigated field. Pipe size was selected to be slightly less than full when carrying the flow rate available on the existing grade. Orifices were drilled in the pipe at 30 degrees from vertical toward the furrow side. Water was forced out of these orifices by a plug in the line. Position and movement of the plug were controlled by attaching it, with a cable through the pipe, to a reel at the inlet end with its rotation rate governed by a geared down, 12 v DC electric motor, regulated in turn by a rheostat. A computer model predicted and field tests corroborated that orifices near the plug had highest flow rates, with flow diminishing in orifices further upstream to zero flow at a distance determined by total flow, orifice, moving downstream at speeds from 3 to 6 miles per hour, flow begins at the maximum rate and then decreases with time until the flow ceases. Effects on flow times and rates from orifices of varying orifice size, total water supply rate and plug speed, and of using multiple plugs and sleeving, are illustrated. Assuming runs that are 300 meters long so the sytem serves 12 ha, thee installation costs would be about $298/ha ($121/acre). If the pipe is left above ground, the life of the sytem is about 10 years. (Baker-FRC)

ECONOMIC ANALYSIS OF WATER MAIN BREAKS,
Army Engineer Waterways Experiment Station, Vicksburg, MS.
T. M. Walski, and A. Pelliccia.
Journal of the American Water Works Association, Vol 74, No 3, p 140-147, March, 1982. 8 Tab, 21 Ref.

Descriptors: *Economic analysis, *Pipes, *Rehabilitation, Water distribution, Water mains, Prediction, Aging, Binghamton, New York.

A simple quantitative method for determining which pipes in a water distribution system should be replaced is based on a history of recorded breaks. This study was initiated by the city of Binghamton, New York, whose 100-year old pipe system needed upgrading. Equations are presented for two approaches: replacing groups of pipes as a unit or on a pipe-by-pipe basis. A set of equations is given to predict the rate of pipe breaks depending on diameter, age, materials, temperature, and previous break history. An economic analysis estimates the cost of repairing a break, including the damage and inconvenience, and whether pipes need immediate or postponed repairs. Factors to consider in pipe replacement are: the cost of a break, price replacement pipe, total length of pipe, length of pipe to be replaced, pipe diameter, previous break history, interest rate, type of pipe, and aging rate of pipe. SITE INVESTIGATION AND MATERIALS SAVE MONEY ON SALLENTE.
World Water, Vol 5, No 4, p 31-32, April, 1982, 3 Fig.

Descriptors: *Hydroelectric plants, *Geological surveys, *Concretes, Embankments, Dam design, Sallente Dam, Spain, Asphaltic concrete, Rockfill dams.

The Sallente Dam, under construction in the Spanish Pyrenees, is interesting for three reasons: its single layer asphaltic concrete upstream facing, the thorough site investigation which resulted in moving the dam's design location 100 m downstream to a site on a much shallower layer of glacial fill, and careful trials of embankment materials suitable for the low temperature and high altitude. Considerable cost savings and increased safety in design were attained as a result of the detailed studies. The dam is 398 m long, 89 m high, and 10 m wide at the crest, with a storage capacity of 6.2 cu hm. (Cassar-FRC)

HYDRO POWERS MINDANAO DEVELOPMENT PLANS,
A. Bingham.
World Water, Vol 5, No 4, p 23, 25, 27, April, 1982. 2 Fig.

Descriptors: *Hydroelectric power, *Water resources development, *Industrial development, Mindanao, Philippines, Agus River, Pulangi River.

Hydroelectric power development on the Agus and Pulangi Rivers in Mindanao, the Philippines, has encouraged economic development on this mineral-rich island, the scene of four centuiries of conflict between the government and a Moslem group. Potential power capacity of the rivers is 900 MW each. On the Agus River, which drops 700 m from Lake Lanao to the sea, two of seven planned dams have been completed, four are under construction, and one is in the planning stage. A 255 MW hydropower plant on the Pulangi River is scheduled for completion in 1985. Further development on the Pulangi faces expensive land acquisition costs. At present 75% of the island's generating capacity comes from hydropower plants with low operating costs. By 1986 the proportion is expected to be 90%. (Cassar-FRC)

THEORETICAL AND EXPERIMENTAL STUDIES ON DYNAMIC STRUCTURE-FLUID COUPLING,
Trabzon Univ. (Turkey).
D. Altinisik, H. Karadeniz, and R. T. Severn.
Proceedings of the Institution of Civil Engineers. Part 2: Research and Theory, Vol 71, No 3, p 675-704, September, 1981. 23 Fig, 4 Tab, 16 Ref.

Descriptors: *Fluid mechanics, *Dams, *Resonance, Earthquakes, Arch dams, Vibrations, Pressure distribution, Hydrodynamics, Finite element method, Computer programs.

The structure-fluid coupling process has been expanded by incorporating a greater variety of finite elements into the computer program, especially the three-dimensional isoparametric element for use with doubly curved structure-fluid interfaces, as exemplified by an arch dam. Tests on cones and thin cylinders containing water and on a model arch dam and reservoir produced results which agreed with calculated results. The objects were subjected to multipoint resonance testing and excitation on a shaking table. A simulated earthquake was applied to the model dam and reservoir. (Cassar-FRC)

MAXIMUM PRESSURE DURING WATER HAMMER ACCOMPANIED BY DISCONTINUITY OF THE FLOW,
V. V. Tarasevich.
Hydrotechnical Construction, No 8, p 784-790, August, 1980. 4 Fig, 6 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 15-18, August, 1980.

Descriptors: *Flow characteristics, *Mathematical equations, Pipelines, *Pipe flow, *Design standards, Pressure heads, High pressure, Cavitation, *Hydraulic engineering.

Discontinuity of a fluid flow is often observed during water hammer in pipeline systems and conduits of hydroelectric stations in the form of various cavities. When these cavities collapse, a considerable increase of pressure can occur. Equations are developed for determining the maximum value of the excess of pressure which occurs upon the collapse of a cavity based on an approximate solution of the problem of water hammer accompanied by discontinuity of flow. These equations make it possible to avoid excessive factors of safety when designing pipelines. (Carroll-FRC)

CALCULATION OF LOCAL SCOUR OF ROCK FOUNDATIONS BY HIGH-VELOCITY FLOWS,
I. I. Taraimovich.
Hydrotechnical Construction, No 8, p 791-797, August, 1980. 4 Fig, 2 Tab, 11 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 19-22, August, 1980.

Descriptors: *Spillways, *Flow characteristics, *Mathematical equations, Jets, *Scour, Rocky soils, Rocks.

In order to solve the problem of local scour in rocky soils occurring beyond spillways with buckets, it is first necessary to know the characteristics of the flow on the spillway for both the nappe and submerged jet. Data from seven spillways are used to develop equations for the determination of the curve of the change in the relative length of the jet with change in the Froude number, the curves of the relative thickness of the jet and core as a function of the relative length of the jet, the curves of the coefficient of breakup of the jet as a function of the Froude number, and the curves of the range of takeoff of the jet from the bucket as a function of the Froude number. Differences between the values determined through these calculations and laboratory values are discussed. (Carroll-FRC)

A FINITE-DIFFERENCE METHOD TO EVALUATE WATER HAMMER PHENOMENA,
Universidad Nacional Autonoma de Mexico, Mexico City. Inst. de Ingenieria.
J. L. Sanchez Bribiesca.
Journal of Hydrology, Vol 51, No 1-4, p 305-311, May, 1981. 1 Fig, 2 Ref.

Descriptors: *Mathematical models, *Mathematical equations, *Finite difference methods, Water hammer, Cavitation.

The method of characteristics has generally been preferred for evaluating water hammer effects. However, in some instances, such as when water column separation is expected, finite-difference procedures may be more suitable. The development of a simple finite-difference method for evaluating water hammer phenomena which is as fast as the characteristics method is demonstrated. The method, which is based on some matrix properties, does not require the solution of a system of linear equations at each of the computing steps, as is usual with finite-difference models. In addition, this method can easily take into account more of the involved factors than are usually considered in the classical procedure. The procedure has been successfully applied to traditional problems. (Carroll-FRC)

THE ROTATING HYDRAULICS OF THE OPEN-CHANNEL FLOW BETWEEN TWO BASINS,
Washington Univ., Seattle. Dept. of Oceanography.
C. Y. Shen.
Journal of Fluid Mechanics, Vol 112, p 161-188, 1981. 10 Fig, 2 Tab, 13 Ref.

Descriptors: *Fluid mechanics, *Open-channel flow, Flow, *Hydraulics, *Flow characteristics, Weirs, Mathematical equations.

Theoretical and experimental investigations of rotating weir flow are presented. Three problems are discussed: constant potential vorticity flow over a submerged weir, in which sill height is below the free surface level of the fluid in the downstream reservoir as opposed to the case in which the free surface is below the sill; controlled zero potential vorticity flow through a channel of irregular cross section; and supercritical separation of the current. In the first problem flow is found to depend on the fluid level in the downstream basin when the fluid level there is high and to become independent of the fluid level downstream as soon as the level falls below a critical height. Transport of the flow decreases whenever rotation rate or upstream potential vorticity is increased. In the second problem transport of the flow increases at some moderate rotations if the channel floor has a cross-channel slope similar to that of the surface of the current. Otherwise, the transport always decreases with rotation rate. In the final problem where the current separates from the left wall of the channel, visual evidence is obtained and measurements of formation of such a boundary current are also secured. Comparisons between theory and experiment for the three cases are generally reasonable except when flow separates in the control section. The theory is not applicable to such separation. (Baker-FRC)

STEADY SHALLOW FLOW OVER A SPILLWAY,

Asian Inst. of Tech., Bangkok (Thailand).
N. S. Sivakumaran, R. J. Hosking, and T. Tingsanchali.
Journal of Fluid Mechanics, Vol 111, p 411-420, 1981. 9 Fig, 11 Ref.

Descriptors: *Fluid mechanics, *Spillways, Overflow channels, Flow, Fluid flow, *Spillway crests, Streamflow, Low flow, *Mathematical equations, Steady flow.

A simple derivation of recent shallow-flow equations is presented, with bed curvature. These equations are applied to steady flow over a high overflow spillway crest, to obtain the head discharge relationship and the crest pressure distribution in good agreement with experimental results. The equations are apparently valid for quite large negative curvatures. Their application to steady flow over a spillway toe indicates that they are valid for positive curvature to a more limited extent. (Baker-FRC)

FINITE-AMPLITUDE STABILITY OF AXISYMMETRIC PIPE FLOW,
Massachusetts Inst. of Tech., Cambridge. Dept. of Mathematics.
A. T. Patera, and S. A. Orszag.
Journal of Fluid Mechanics, Vol 112, p 467-474, 1981. 4 Fig, 1 Tab, 14 Ref.

Descriptors: *Pipe flow, *Fluid mechanics, Flow, Pipes, Pipelines, *Mathematical equations, Navier-Stokes equations, Reynolds number, *Axisymmetric pipe flow.

Spectral methods were used to investigate numerically the behavior of finite-amplitude axisymmetric disturbances in pressure driven pipe flow. The basic question concerns the existence of finite-amplitude equilibrium states of this flow. If such states do not exist, then pipe flow is stable to all axisymmetric disturbances. No evidence was found of finite-amplitude equilibria at any of the wavenumber/Reynolds number combinations investigated, with all perturbations decaying on a time scale much shorter than the diffusive (viscous) time scale. Decay was obtained where amplitude-expansion perturbation techniques predict equilibria, thus indicating that these methods are not valid away from the neutral curve of linear stability theory. The results of this study indicate that the method of false problems is not a valid procedure for investigating finite-amplitude axisymmetric perturbations to pipe flow. (Baker-FRC)

DETERMINATION OF THE OPTIMAL HEIGHT OF THE BUCKET LIP OF A SKI-JUMP SPILLWAY,
A. N. Butakov.
Hydrotechnical Construction, Vol 15, No 6, p 335-341, June, 1981. 7 Fig, 1 Tab, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 19-23, June, 1981.

Descriptors: *Spillways, *Design criteria, Hydraulics, Dams, Equations.

Equations are developed for determining the optimal lip height and corresponding angle of descent of a water jet from the lip for providing the maximum flight distance of the jet. These equations are suitable for calculating cantilever ski-jump spillways. Three examples are given to illustrate the equations in practical situations. The first example was that of determining the position of the lip of the chute providing the greatest flight of the jet. The second proposed determining the optimal position of the spillway lip providing maximum flight of the jet and the distance of the flight in the case of a discharge of floodwaters over a spillway of standard crest shape. In this case the effect of aeration of the flow on the flight distance of the jet had to be taken into account. The third case involved examining spillway designs in order to provide the greatest flight distance of the jet from the dam site in the case of an arch dam supporting a head of 225 m. Spillway variants were an overflow spillway with a crest head of 5.5 m and a rectangular spillway passing through the dam at a depth of 100 m from the upper pool level. (Cassar-FRC)

CALCULATION OF LARGE UNLINED CANALS,
R. I. Samedov.
Hydrotechnical Construction, Vol 15, No 5, p 289-293, May, 1981. 4 Tab, 15 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No. 5, p 25-28, May, 1981.

Descriptors: *Canal design, *Hydraulic properties, *Soil physical properties, *Scour, Soil mechanics, Channel scour, Diversion channels, Azerbaidzhan, Silting, Bank erosion, Soil stability, Stable channels, Deformation, *Geokchai River, *USSR.

Calculation of hydraulic properties of large unlined diversion canals should be based on physical and mechanical properties of the soils. For cohesive soils the angle of internal friction and the slope angle are frequently not equal. The diversion canal of the Geokchai River in Azerbaidzhan SSR was investigated. This canal receives unregulated river runoff. Hydraulic parameters and physical and mechanical properties of the soils for eight reaches of the 13 km canal are presented in a table. Scouring is occurring in the 2-5 km reach, and silting and bank deformation is found in the 10-13 km stretch. The scoured section has a relative channel width 10 fold less and a parameter M of about 1.4 in the scouring section and 0.5 in the silting section. The discharge was the same in all sections of the canal. Therefore, the parameter M cannot be used alone to characterize channel deformation. (Cassar-FRC)

HYDRAULIC MODEL STUDIES OF LANDSLIDE-GENERATED WATER WAVES-MORROW POINT RESERVOIR,
Bureau of Reclamation, Denver, CO. Engineering and Research Center.
C. A. Pugh.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224452, Price codes: A04 in paper copy, A01 in microfiche. Report REC-ERC-82-9, April 1982. 60 p, 16 Fig, 2 Tab, 7 Ref, 2 Append, including 156 p of microfiche.

Descriptors: *Landslides, *Hydraulic models, *Wave height, *Model studies, Waves, Solitary waves, Reservoirs, Bores, Dams, Dam overtopping, *Marrow Point Dam, Colorado.

Morrow Point Dam is a double-curvature, thin-arch concrete dam located on the Gunnison River 40 km east of Montrose, Colorado. A number of major landslide areas are located upstream from the dam. Under certain conditions it is possible that a slide could break free and plunge into the reservoir at velocities greater than 30 m/s. A physical model study was conducted to determine the magnitude of waves in the event such a landslide occurs. The model of 4.8 km of the reservoir and 1.3 km of the downstream canyon was constructed to an undistorted scale of 1:250. A wedge-shaped slide was used. It was found that the direction of the landslide as well as the volume of water displaced and slide velocity are important to the wave height in the vicinity of the slide. Waves directly in line with the slide direction were two to three times higher than waves not in line with the slide. Waves distant from the slide were solitary waves. Waves in the river downstream were bore waves. The maximum wave height at the dam due to a slide at one of the selected sites was 7 m. Nondimensional relationships were developed to predict wave heights for Morrow Point Reservoir and other cases as a function of slide velocity, water depth at the slide, volume of water displaced, and distance from the slide. EROSION BY PLANE TURBULENT JETS,
Alberta Univ., Edmonton.
N. Rjaratnam.
Journal of Hydraulic Research, Vol 19, No 4, p 339-358, 1981. 11 Fig, 2 Tab, 20 Ref.

Descriptors: *Erosion, *Jets, Dimensional analysis, Scour, Channel erosion, Mathematical studies, Hydraulics, Sand, Gravel, Laboratory studies, *Hydraulic engineering, Soil types.

Erosion of loose beds of sand, gravel, and such other materials as clay and weak rock is a problem of considerable importance in hydraulic engineering. Such erosion may be caused by flow concentration, local flow acceleration, secondary flow, vortices, or high velocity jets. Previous studies have shown that at some point in the erosion process, the maximum depth of erosion or any other length scale of the erosion process increases linearly with the logarithm of time from the start of the erosion process and that, as times increases, the characteristic lengths eventually reach an end or asymptotic state. This paper presents the results of a continuing study of erosion caused by submerged plane wall jets of air and water on beds of sand and polystyrene and by submerged impinging plane jets of water and air on beds of sand. Dimensional analysis was used to study the characteristic features of the scroured bed in the asymptotic state. The maximum depth of erosion for the asymptotic state, in terms of the height of impingement, was found to be primarily a function of the densimetric Froude number and the total thickness of the jet. The functional relationship between these factors was different for air-sand and water-sand systems, apparently due to the mode of transport of the eroded bed material out of the scour hole. The profile of the eroded bed, at least in the scour hole portion, was found to be similar for the air and water series. (Carroll-FRC)

AN INVESTIGATION OF A JET-ASSISTED HYDRAULIC JUMP,
University of Wales Inst. of Science and Technology, Cardiff. Dept. of Civil Engineering.
P. W. France.
Journal of Hydraulic Research, Vol 19, No 4, p 325-337, 1981. 12 Fig, 5 Ref.

Descriptors: Dam design, *Hydraulic jump, *Jets, Fluid mechanics, Flow patterns, Kinetic energy, *Spillways.

Dissipation of the kinetic energy of the flow of water over a dam spillway is essential if dangerous scour in the natural channel below the structure is to be avoided. The most effective and widely used method for reducing the energy of the falling water is the formation of a hydraulic jump in a stilling basin at the toe of a spillway. Baffle piers, chute blocks, and sills are the traditional means used to stabilize the jump. The use of jets of water issuing from underneath the formation of a hydraulic jump which requires a smaller tailwater depth. theoretical analysis of the jet-assite hydraulic jump is presented in graphic form and verified experimentally using a specially designed model which fits into a small closed-circuit laboratory flume. Although the stabilization of the jump is dependent on a number of parameters, the angle of inclination of the jets appears to have the most significant effect. (Carroll-FRC)

SURVEY OF PRESENT KNOWLEDGE ON CAVITATION IN LIQUIDS OTHER THAN COLD WATER (THERMODYNAMIC EFFECT),
International Association of Hydrological Sciences, Paris (France).
J. Bonnin, M. L. Billet, F. G. Hammitt, and B. Chaix.
Journal of Hydraulic Research, Vol 19, No 4, p 278-305, 1981. 4 Fig, 31 Ref.

Descriptors: *Cavitation, *Thermodynamics, *Fluid mechanics, Hydraulics, Evaporation, Water pressure, Mechanical equipment, *Temperature effect.

Although in the past the study of bubble behavior from a purely mechanical point of view was considered adequate for explaining the main features of cavitation, it is now understood that thermodynamic effects may interfere with bubble behavoir when the physical properties of a liquid are other

than those of cold water. These thermodynamic effects are primarily the result of the greater specific mass of the vapor and the heat of vaporizaiton. This paper summarizes the current state-of-the-art with respect to research regarding thermodynamic effects on cavitation. The required net positive suction head for pump tests in hot water and other liquids is less than that for tests with cold water, and cavitation erosion is less violent. Cavitation inception is delayed by thermodynamic effects, which depend on numerous parameters. The heat of vaporization is drawn from the surrounding liquid, causing a drop in temperature in the cavity which is connected with a lower pressure of vaporization. Adequate grouping of parameters permits comparison between fluids and test facilities, and even transporition of test results between different models, such as ogives, venturis, and pumps. Cavitation erosion is influenced by a wide range of parameters, and it is not yet possible to classify the amount and rate of this erosion. (Carroll-FRC)

AN EVALUATION OF TWIN WELLS FOR USE WITH WATER SOURCE HEAT PUMPS,
Louisana State Univ., Baton Rouge. Dept. of Civil Engineering.
J. R. Buller, Jr.
M.S. Thesis, May 1981. 96 p, 15 Fig, 51 Tab, 20 Ref. OWRT A-046-LA(2).

Descriptors: *Heat exchangers, *Heat transfer, *Pump wells, *Cost-benefit analysis, Drilling, Heated water, Cooling, Wells, Pump testing, Pumping tests, Pumps, Cost analysis, Air conditioning, Economic feasibility, Economic evaluation, Economic efficiency, Input-output analysis, Water use, Saline water intrusion, Seepage, Groundwater, Installation, Civil engineering, Dug wells, Well water, Louisiana.

A cost-effectiveness assessment in two Louisiana Parishes on water source heat pumps (with a set of twin wells supplying the groundwater heat source/sink) and conventional air source heat pumps revealed that the former will reduce operating costs 20-30% relative to the latter. The installation costs of water source heat pumps are greater than conventional systems due to the drilling cost of the supply and recharge wells. The total well drilling depth controls the cost-effectiveness. The return of reusable heat pump effluent water via the twin well system will avoid harmful side effects of salt water intrusion and excessive lowering of water levels caused by groundwater withdrawals. The break-even drilling depths for water source heat pumps was 90 and 100, 170, and 125 and 80 ft for residential, commercial, and industrial pumps, respectively, for the two Parishes. For depths greater than the break-even point, conventional systems were computed to be less costly. However, high efficiency water source heat pumps having heating and cooling coefficients of performance of 4.5 and 4.0, respectively, are possible. The economic break-even point drilling depth may be increased if the costs of such pumps are below $250, $150, and $100 per ton for residential, commercial, and industrial heat pumps, respectively. NORTHERN ELBE CULVERT,
Hamburg City Drainage (Germany, F.R.).
E. Kuntze.
Water Science and Technology, Vol 14, No 1/2, p 263-268, 1982. 3 Fig.

Descriptors: *Culverts, *Sewer systems, *Wastewater collections, Water conveyance, Storm water, Elbe River, *Hamburg, *Germany, Drainage systems, Air cushion culverts.

An air cushion culvert under the northern Elbe River is part of a sewer reconstruction in the city of Hamburg, West Germany. A large air pocket formed by pumping air into the pipe between bulkhead walls allows adjustment of the discharge cross section to fit variable flow. This procedure maintains a flow velocity high enough to prevent sediment accumulation. The Elbe culvert is 610 m long, with inflow and discharge diameters of 3500 mm and 2 pipelines of 2400 mm each. Equipment for operation of the culvert includes inlet and outlet piping in the shape of a siphon, air supply mechanisms, filling depth control, and ventilation. Trial operation using clean water begun in autumn of 1980 indicated that flow velocities had to be corrected upwards by 10-15%. (Cassar-FRC)

ESTIMATING WATER FLOW UNDER GATES,
A. Zanker.
International Water Power and Dam Construction, Vol 33, No 12, p 50-51, December, 1981. 2 Fig.

Descriptors: *Flow rates, *Mathematical equations, *Gates, Nomograms, Hydraulics, Water flow, Water levels.

The flow of water under a vertical gate may be assumed to be the same as the flow of water through a square orifice, provided that the opening height is small when compared with the upstream and the downstream water levels. Direct use of the equation for the rate of flow is made difficult by the uncertainty involved in measuring the depth of water at the vena contracta. Solution of the equation generally is accomplished through a lengthy procedure involving computation of the upsteam water level to gate opening height ratio and determination of two coefficients dependent on this ratio. This paper presents a simple method of estimating the flow rate under a straight gate using a nomogram. Both the nomogram and instructions for its use are included. (Carroll-FRC)

USE OF TWIN WELLS AND WATER-SOURCE HEAT PUMPS FOR ENERGY CONSERVATION IN LOUISIANA,
Louisiana Water Resources Research Inst., Baton Rouge.
R. G. Kazmann.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-232018, Price codes: A05 in paper copy, A01 in microfiche. Technical Report No 9, December, 1981. 68 p, 28 Fig, 22 Tab, 16 Ref, 1 Append. OWRT A-046-LA(3).

Descriptors: *Heat exchangers, *Heat transfer, *Wells, *Pump wells, *Cost-benefit analysis, Heated water, Drilling, Cooling, Pump testing, Pumping tests, Cost analysis, Civil engineering, Input-output analysis, Air conditioning, Water use, Economic efficiency, Economic evaluation, Aquifer management.

The feasibility of the installation and operation of twin wells and water source heat pumps was evaluated for two typical Louisiana parishes. The use of such a system for energy conservation was determined to be safe and feasible. The two wells should be used in an alternating manner as the water source; one for production, one to return water to the aquifer. This mode of operation is used to eliminate any impact on groundwater levels, and to prevent interfering with other users of the same aquifer. Tables are included for determining the physical spacing between the production and return wells for any combination of aquifer thickness, length of season, and rate of water production, such that the returned water will not appear in the production stream. Economic analyses covered residential, commercial, and industrial applications for the two parishes. All hydrogeological data required for the development of preliminary designs are provided on the included maps. It is concluded that a water-source heat pump and a single well combination is almost always the most significant efficient installation to produce the required heating and cooling. In many locations in the two parishes, the twin well heat pump system will be economical. (Zielinski-MAXIMA)

OPTIMUM DEPTH AND SPACING OF SUBSURFACE DRAINS,
Marathwada Agricultural Univ., Parbhani (India).
H. S. Acharya, and D. G. Holsambre.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 108, No IR1, p 77-80, March, 1982. 1 Fig, 4 Ref.

Descriptors: *Mathematical studies, *Subsurface drains, *Drain spacing, *Construction costs, Mathematical equations, Drains, Tile drains, Drainage systems, Subsurface drainage, Tile drainage, Drainage practices, Water table profiles.

Proper choice of depth and spacing of drains can help to minimize the cost of installing a subsurface drain for use in agriculture. An analytical solution which yields formulas for the direct determination of depth and spacing that minimize the cost is presented. The present solution does not require numerical techniques, but rather utilizes various constraints on the water table height in the Hooghoudt's formula for estimating water table heights between tile drains. The optimum location for the subsurface drain is taken from one of the vertices of the set of feasible solutions to two simple equations, and the optimum solution is obtained by direct verification. DISPERSION IN TUMBLING FLOW,
Canada Centre for Inland Waters, Burlington (Ontario).
S. Beltaos.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 591-612, April, 1982. 10 Fig, 4 Tab, 22 Ref.

Descriptors: *Flow profiles, *Turbulent flow, Flow measurement, Model studies, Mathematical equations, Streams, Rivers, Hydraulics.

Results are presented of several dispersion tests in a rectangular flume, plus an analysis based on two different theoretical models. The rectangular flume was divided into a series of pools by placing triangular weirs at equal distances along the flume, causing a flow pattern considered to represent a first approximation to the tumbling flow regime seen in prismatic laboratory channels and in many rivers. The study allowed several conclusions. The time of travel in a series of pools and falls can be calculated in a straight-forward manner. It is equal to the time of travel for one pool times the number of pools. With suitable choice of the dispersion parameters, the river dispersion model provides satisfactory predictions of observed dispersion characteristics. Moreover, the dispersion parameters appear to correlate plausibly with hydraulic stream characteristics. Thus, the river dispersion model may eventually prove realistic for mountain stream dispersion. However, field data are needed to enable practical application. With suitable choice of the pool residence time, the storage dispersion model gives satisfactory predictions of dispersion characteristics. However, it is unclear whether this model is realistic, and its partial agreement with the data may have been fortuitous. (Baker-FRC)

OUTFALL DIFFUSER BEHAVIOR IN STRATIFIED AMBIENT FLUID,
Michigan Univ., Ann Arbor. Dept. of Civil Engineering.
S. J. Wright, D. R. Wong, K. E. Zimmerman, and R. B. Wallace.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 483-501, April, 1982. 12 Fig, 2 Tab, 19 Ref.

Descriptors: *Wastewater outfall, *Mathematical equations, Stratification, Mixing, Destratification, Model studies, Hydraulics.

A method is presented for the preparation of design charts for estimating the mixing behavior from outfall diffusers in stagnant stratified ambient fluids. Numerical analyses by traditional integral methods which consider the interaction and merging of individual port discharges are used to predict the diffuser behavior. Predictions for the maximum height of plume rise and minimum dilution at that point are presented in the form of design curves. Experimental data for the cases of a single and opposing rows of horizontal ports are presented and compared to the numerical results. Additional data on the thickness and vertical location of the horizontally spreading layer developed after the maximum rise is reached are presented. The numerical model was found to be inaccurate for cases of discharges with significant initial momentum. A criterion is developed to indicate when this effect will be important. (Baker-FRC)

FLOW RESISTANCE IN WIDE RECTANGULAR CHANNELS,
New Univ. of Ulster, Coleraine (Northern Ireland). School of Civil Engineering.
W. R. C. Myers.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 471-482, April, 1982. 5 Fig, 2 Tab, 13 Ref.

Descriptors: *Flow resistance, *Open channels, Pipe flow, Mathematical equations, Hydraulics, Flow friction, Hydrantic friction, Reynolds number.

This work is part of a wider study into flow resistance in channels that have floodplains. Flow over the floodplains is characterized by low depths and velocities, low Reynolds numbers, high relative roughness and large width-to-depth ratios. Flow in the central channel will exhibit greater depths, velocities and Reynolds numbers, lower relative roughness, and smaller width-to-depth ratios. The work is aimed at investigating the variation of friction factor with Reynolds number and width-to-depth ratio for hydrodynamically smooth flow. Friction factors have been measured in a rectangular open channel covering width-to-depth ratios of 1-35 and Reynolds numbers of 6,000-168,000. The relationship between friction factor and Reynolds number has been found not to conform to the pipeflow relationship. On the average open channel factors are around 8% higher than those for pipes at the same Reynolds number. The results have been compared with other investigations, showing agreement on the general form of the friction factor and Reynolds number relationship, but differences of the numerical constraints in the equation. The relationship of friction factor to width-to-depth ratio has been shown to be complex, influenced by secondary circulation and channel shape. The methods of Pillai and Kazemipour and Apelt have been applied to the data, showing that their methods reduce the divergency between the open channel data and the pipeflow equation to less than 2%. Differences may be due to the inadequacy of the methods in taking into account the effects of secondary circulation. (Baker-FRC)

FLOW UNDER WEIR ON SCOURED BED,
Uttar Pradesh Irrigation Research Inst., Roorkee (India). Tehi Dam Div.
D. Kumar, G. C. Mishra, and S. Chandra.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 529-543, April, 1982. 8 Fig, 16 Ref.

Descriptors: *Weirs, *Flow profiles, Flow pattern, Flow rates, Barriers, Dams, Flow measurement, Flow characteristics, Flow around objects, Scour, Channel scour.

Using conformal mapping techniques an approximate analysis for seepage flow under a weir, resting on isotropic porous medium of infinite depth, with a vertical sheet pile at the toe and segmental circular scour commencing from the downstream end of the apron, has been obtained. An exact analysis for semicircular scour, using conformal mapping, is also presented. A comparison is made between the results of approximate and exact analysis for the semicircular scour of various depths. The maximum exit gradient is shown to be increased by about 75% in the case of semi-circular scour. For semi-circular scour profile, where s is the depth of sheet pile and b is the width of the floor, as s/b increases the point of maximum exit gradient shifts away from the sheet pile. The exit gradient distribution obtained from approximate analysis is very close to the one given by the exact analysis, but the potentials at salient points under the apron obtained from the two analyses compared closely for values of s/b up to 0.1. These analyses will be helpful to decide the value of safe exit gradient of hydraulic structures on permeable foundation. (Baker-FRC)

CALCULATION OF COMPLETE INTERCEPTION OF GROUNDWATER FLOW TO 'FULLY PENETRATING' EXCAVATIONS,
V. M. Grigor'ev.
Hydrotechnical Construction, Vol 15, No 6, p 351-356, June, 1981. 4 Fig, 8 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 29-32, June, 1981.

Descriptors: *Seepage control, *Dewatering, *Excavation, Aquicludes, Aquifers, *Well hydraulics, Vacuum wells, Wells, fully penetrating wells, Capillary water, Pumping, Groundwater management, Interception, Design criteria.

Equations for calculation of complete interception of groundwater flow by vacuum wells are presented. These are useful in design and operation of wells and pumps for dewatering excavations which extend through an aquifer to the underlying aquiclude. The calculations include the physical seepage patterns and the temporal changes in water and air discharges. To simplify the calculations the dynamic level in the well and the vacuum in the above-water space are assumed constant. (Cassar-FRC)

RESONANCE IN HYDROPOWER STATIONS,
Chemin des Vignes, Pully Lausanne (Switzerland).
C. Jaeger.
International Water Power and Dam Construction, Vol 34, No 1, p 20-22, January, 1982. 16 ref.

Descriptors: *Hydroelectric plants, *Resonance, Mechanical equipment, *Design criteria, Pressure conduits, Turbines.

Possible resonance in pressure conduits can present difficulties for hydropower engineers. Several unforeseen pressure surges which occurred recently in large hydropower stations have caused increasing concern. Basic research in this area is summarized. The ability to foresee or predict resonance in hydropower stations calls for consideration of two points: the geometry of the system of conduits and the boundary condition. In some cases the period of the excitor is determined by its own physical characteristics. The calculations are far more difficult when there is reciprocal interaction between the boundary conditions and the system of conduits, causing auto-oscillations. When the period of the excitor is known, the danger of possible resonance can be checked on a model which could be either a laboratory model or a computer model. Higher harmonics developing in a system of three converging conduits can be analyzed with the generalized theory of waterhammer waves. It is likely that the location of the zero point next to the point of insertion of the three conduits is important for the formation of a system of steady waves. Any prediction on possible resonance occurrring in a system of hydraulic conduits requires spotting probable excitors. (Baker-FRC)

TURBINES FOR ITAIPU,
Itaipu Binacional, Rio de Janeiro (Brazil).
J. De Moraes, J. Rodriguez, J. H. Gummer, and F. Del Brenna.
International Water Power and Dam Construction, Vol 34, No 1, p 28-33, January, 1982. 9 Fig, 5 Tab, 23 Ref.

Descriptors: *Turbines, *Testing procedures, Mechanical equipment, Quality control, *Hydraulic turbines, Construction, *Design criteria, Hydroelectric plants, Dams, Itaipu, *Brazil.

A model test for turbines is described, which is used for draft tube and spiral case pressure fluctuations. In measuring draft tube oscillations, two separate phenomena were observed. These were: a rotating core which obviously gives fluctuations in pressure when measured at a fixed point in the draft tube but does not result in a change of net head, and possible pulsations of that core which result in a change of net head across the turbine and hence a change of flow. A pure rotational draft tube vortex presents no problem, but a pulsating vortex does. Specific requirements are detailed for runners, shaft, bearings, shaft seal, lower bend, spiral case and stayring, head cover and bottom ring, regulating mechanism, draft tube liner and pit liner, governor, and quality control and inspection. FIELD TESTING AND OPTIMIZING EFFICIENCY OF HYDRO TURBINES,
Department of Energy, Idaho Falls, ID. Idaho Operations Office.
L. H. Sheldon.
International Water Power and Dam Construction, Vol 34, No 1, p 22-28, January, 1982. 10 Fig, 8 Ref.

Descriptors: *Hydroelectric plants, *Evaluation, Mechanical equipment, *Turbines, *Testing procedures, On site studies.

The advantages and techniques of conducting both absolute and relative efficiency tests of hydraulic turbines are outlined. The performance of large turbines is usually determined initially in model tests. However, prototype turbine installations always show some differences from their models, which alter their performance characteristics. Turbine model tests are still needed to determine the full performance capabilities of a particular machine, no matter what prototype testing is done. Model efficiency curves are usually determined to a high degree of accuracy. Inherent differences between a model with its test-stand instrumentation and a prototype with its powerhouse features cause some differences between the efficiency curves of the two. These differences are caused by such factors as efficiency stepup, powerhouse head determination, site differences, manufacturing differences, deflection differences, and wear. The two basic types of efficiency testing are the absolute and the relative, denoting whether the discharge is measured absolutely or in relation to some other known parameter. The absolute methods include: Gibson, Allen salt velocity, weir, piezometer traverse, current meter, sonic, and thermodynamic. Results from index testing may be used in several ways. (Baker-FRC)

WATER SYSTEM EFFICIENCIES,
F. Gay.
Water Well Journal, Vol 36, No 3, p 54-55, March, 1982.

Descriptors: *Pumps, *Energy, Submersible pumps, Energy conservation, Operating principles, Pump efficiency.

The operating principles of jet pumps and submersible pumps are reviewed as guidelines for designing energy-efficient water systems. Jet pumps are available for shallow or deep well use. The shallow well pump consists of a centrifugal pump in series with an ejector pump. Dependent on atmospheric pressure for moving water from the well level to the venturi tube inlet, shallow well pumps are limited to 25 ft in practice. A deep well jet pump operates in a similar manner, except that the ejector pump is submersed. The practical limit for deep well jet pumps is 180 ft. Submersible pump consist of several individual centrifugal pumps mounted in series. They are more efficient and initially more expensive than jet pumps. Efficiency of a pumping system will be maixmal if pumps and pressure tanks of proper capacity are chosen, proper pressure switch settings are selected (normally 20/40 psi for piston and shallow well pumps and 30/50 psi for submersibles and deep well jets), piping size is selected to minimize friction loss, and motor efficiencies are improved. WATER HAMMER,
E. Butts.
Water Well Journal, Vol 36, No 3, p 63-65, March, 1982. 2 Fig, 3 Ref.

Descriptors: *Water hammer, *Flow control, *Pipe flow, Pipelines, Hydraulic systems, Pumping, Flow velocity, Water flow.

Water hammer is caused by the sudden stopping of flowing water in a pipe system. Formulas are given for calculating water hammer and for understanding the factors in its formation. Major components in the formulas are pipeline velocity, time of flow stoppage, and length of pipeline. Maximum surge pressures are obtained in pipes made of unelastic material. Water hammer can be minimized by operating a system properly--eliminating air entrapment in the pipeline, allowing sufficient time in closing valves so that the flow pattern can modify, and avoiding excessive flow velocity. Devices or construction materials available for protection against water hammer are quick-closing check valves to prevent reverse flow acceleration, water hammer arrestors (a capped riser or small hydropneumatic tank), surge anticipator valves, and strong flexible pipe. THERMOCLINE DRAWDOWN ABOVE COOLING WATER INTAKES,
Ontario Hydro, Toronto. Flow Systems Lab.
E. E. M. Elsayed.
Canadian Journal of Civil Engineering, Vol 9, No 1, p 31-37, 1982. 7 Fig, 2 Tab, 3 Ref.

Descriptors: *Thermocline, *Drawdown, Cooling water, Mathematical equations, Design criteria.

The purpose of this work was to present the derivation of an analytical expression relating the critical discharge associated with the incipient thermocline drawdown condition to the thermal structure of the water body and the geometric properties of the intake structure, and then to present experimental results and field measurements to verify this relationship. The expression was developed for an incipient drawdown of a thermocline into a submerged intake equipped with a circular cover. For specific thermal conditions at the intake location, the relationship found can be used to determine limiting design requirements for the geometry of the intake structure to prevent withdrawal from the upper warm water layer. The use of this equation may also be extended to other engineerng applications involving causes of stratification other than temperature differences, such as salinity differences or variations in suspended sediment load. USE AND DESIGN FEATURES OF THE PUMP UNIT OF THE UVV-3-6KM VACUUM GROUNDWATER LOWERING INSTALLATION,
A. L. Zatevakhin, L. A. Titov, K. S. Bogolyubov, and B. S. Krakovskii.
Hydrotechnical Construction, Vol 15, No 7, p 405-410, 1981. 4 Fig, 1 Tab, 4 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 7, p 19-23, July, 1981.

Descriptors: *Pumps, *Dewatering, *Groundwater level, Construction methods, Construction equipment, Design criteria, Performance evaluation.

The UV-3-6KM pump unit for lowering groundwater levels is described. This monoblock pump unit is smaller in weight and capacity than the well-known UVV-2 installation but belivers water to increased heights. Detailed descriptions and drawings of the new pump are given. Maximum water delivery is 12.5 liters per sec; maximum air delivery at a vacuum in the suction header of 0.075 MPa, 6.2 liters per sec; installed ejector capacity, 15 kW; weight, 790 kg; and size, 1800 x 780 x 1400 mm. It includes a 100 meter long suction header and 100 wellpoints. (Cassar-FRC)

USE AND INVESTIGATION OF WATER-JET PUMPS (EJECTORS) AT THE CHIRKEY HYDROELECTRIC STATION,
Z. L. Zelenevskii, V. V. Kononov, and I. N. Lukin.
Hydrotechnical Construction, Vol 15, No 7, p 411-413, 1981. 2 Fig, 1 Tab. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 7, p 23-25, July, 1981.

Descriptors: *Pumps, *Hydraulic machinery, Jet pumps, Vibrations, Noise, Cooling, Hydroelectric plants, Chirkey hydroelectric station, USSR.

Water jet pumps were installed in parallel with the centrifugal pumps at the Chirkey hydrostation, USSR. The pumps are used to cool the generator and transformer. Other possible uses of water jet pumps at hydrostations are circulation of the water supply, pumping of the dam plug, emergency pumping of the hydrostation, drainage of the powerhouse, pumping water from turbine covers, and priming centrifugal pumps. Operating at a wide range of pressures (1.50-2 MPa), the pumps have efficiencies of 34-41%. The ejector pumps use about half the electrical energy of other pumps with similar capacity and reduce personnel requirements by 3%. Since the ejectors are very noisy (up to 107 dB), noise protection is required. Strong vibrations necessitate anchoring the pumps and connected pipes to walls or floors by steel anchors. (Cassar-FRC)

USING PUMPS AS SMALL TURBINES,
McGraw-Edison Co., Mountainside, NJ.
L. Shafer, and A. Agostinelli.
International Water Power and Dam Construction, Vol 33, No 11, p 58-59, November, 1981. 3 Fig.

Descriptors: *Pumps, *Turbines, Design criteria, Pump turbines, Hydroelectric plants, Cavitation, Performance evaluation.

Greater use of centrifugal pumps as turbines has been seen as a result of the increased interest in small hydro. Since these pumps are mass produced, they can cover a wider range of applications at a lower cost than comparable purpose-built turbines. The performance of a turbine can be predicted accurately from one set of operating conditions to another, and new turbine designs can be developed from existing designs. When a pump operates as a turbine, its mechanical operation is smooth and quiet, its peak efficiency as a turbine is essentially the same as its peak efficiency as a pump, and the head and flow at the best efficiency point as a turbine are higher than the pump input power at its best efficiency point. Just as with the pump, at any point in the machine where the local pressure drops to the vapor pressure of the liquid, cavitation damage can occur when vapor is formed. In most cases no design changes or modifications are needed for a pump to operate as a turbine. There is a rapidly increasing number of successful installations of pumps as power turbines. One such site is in New York City, where a 36 in pump is being used as a turbine and has been running without trouble since 1949. (Baker-FRC)

GENERATING POWER FROM COMPENSATING FLOW.
International Water Power and Dam Construction, Vol 33, No 11, p 59-60, November, 1981.

Descriptors: *Hydroelectric plants, Compensation, Powerplants, *Motz, *Rhone River, *France, Minimum flow, Hydropower units, Seasonal variation, Snowmelt, *Hydroelectric power.

A conventional hydroelectric powerplant was constructed on the Rhone River at Chautagne. It has two bulb units rated at 45 MW under a head of 17 m and a flow of 350 cu m/sec each. Following customary European practice, the station was constructed 'in the dry', and water is conveyed to it through a canal, bypassing a short section of river. A minimum flow, in this case 10 cu m/sec, is required to be maintained in the original flow channel, and is called the compensating flow. At Motz, few km above the Chautagne power station, a small hydro plant was installed to produce about 10 GWh per year from two turbines rated at 750 kW at a head of 9.5 m. One unit will operate in winter and both in summer, when the snowmelt increases flow. The generators (induction machines) are small and are less expensive than corresponding synchronous machines. The reactive power needed for the machines is supplied by capacitors. Monitoring and command programming differ slightly from those for other systems. Performance and condition are monitored by a programmable microprocessor covering parameters such as oil fow, temperature, speed, current, and voltage. The unit also switches the generators on and off according to a program which can be

modified on site. Motz will eventually be operated by remote control. The design will probably be replicated at other stations which the Compagnie Nationale du Rhone is planning to build. Use of compensating flow for power generation is being promoted by environmentalists in France. (Cassar-FRC)

USING PUMP CURVES AND VALVING TECHNIQUES FOR EFFICIENT PUMPING,
Hilsdon and Sonnenburg, Memphis, TN.
C. W. Hilsdon.
Journal of the American Water Works Association, Vol 74, No 3, p 157-159, March, 1982. 7 Fig, 2 Tab.

Descriptors: *Pumps, *Design criteria, *Graphical analysis, Pumping head, Pressure head.

System head curves are given to aid in pump selection for single- and multiple-pump installations. The total dynamic head (the difference between suction and discharge heads) is beneficial in determining the approximate pump size and required horsepower. The system head curve is developed by determining the total dynamic head at various capacities above and below the normal operation condition. The curve may be expanded to consider the variation in water surface levels of the storage vessels on both sides of the pump and to consider the effects of capacity regulation devices. System head curves are given for five situations: a typical single-stage constant-speed pump, variation of impeller diameter at constant speed, variation of centrifugal pump speed, parallel operation of more than one centrifugal pump, and series operation of more than one centrifugal pump. In general, for parallel centrifugal pump operation the capacities can be added, and for series centrifugal pump operation the heads can be added. (Cassar-FRC)

PUMP INSTALLATIONS FOR REVERSE OSMOSIS SYSTEMS,
Weber Industries, Inc., St. Louis, MO.
W. Gordon, and R. Hensel.
Water Well Journal, vol 36, No 3, p 56-58, March, 1982. 1 Fig.

Descriptors: *Reverse osmosis, *Pumps, Equipment, Performance evaluation, Hydraulics, Matematical equations, Design criteria, Cavitation.

Suggestions for operating pumps in a reverse osmosis system are given. Pumps intended to supply multiple outlets must be sized according to the pressure and capacity at the extreme outlet. The booster pump, which develops the pressure required for the reverse osmosis process, must be operated dry, with insufficient pressure, or with air in the system. Available net positive suction head (the difference between total suction head at the pump suction and the vapor pressure of the liquid) must be equal to the required net positive suction head. The pump must be completely flooded before start-up. A diagram illustrates a typical priming system. All air must be expelled from the system when cartridges are changed. The supply line should exceed the inlet thread size 1 or 2 sizes. (Cassar-FRC)

CALCULATION OF THE TEMPERATURE REGIME OF HYDRAULIC FILL DAMS DURING THEIR CONSTRUCTION,
B. M. Skhundin, and Y. A. Popov.
Hydrotechnical Construction, Vol 15, No 5, p 273-278, May, 1981. 3 Fig, 11 Ref. Translated from Gidroteknicheskoe Stroitel'stvo, No 5, p 15-18, May, 1981.

Descriptors: *Hydraulic fill, *Dam construction, *Soil temperature, Earth dams, Soil mechanics, Frozen ground, *Siberia, Boguchany Dam, *Temperature, Design criteria, Freezing, Thawing, Model studies, Mathematical models, Heat transfer, Ice.

A mathematical model permitted greater understanding of the temperature regime of the Boguchany hydraulic fill dam in Siberia. If the hydraulic filling season is started 22 days after the April 23 establishment of positive air temperatures, as the design specified, a 0.4-0.6 m thick thawed layer is present on the surface of the blocks at the start of filling. Complete thawing of the ground occurs by August 29. If the hydraulic filling season is started on April 23, a 0.6-0.8 m thick frozen soil layer remains in the block by the end of the hydraulic filling season. Improvements in construction methods suggested by the model were (1) remove thawed soil by bulldozers (2 cuts) so that filling can begin May 6 instead of May 15 and complete thawing can occur by the end of the season, (2) retain snow on the surface to reduce the depth of seasonal freezing, (3) heat the soil with an electric cable to reduce the depth of seasonal freezing, and (4) develop methods of using the natural heat stored in the soil of the borrow pit and in the water body. These measures extend the hydraulic filling season beyond the frost-free limits. (Cassar-FRC)

LARGE-SCALE EXPERIMENTAL INVESTIGATIONS OF FAILURE OF AN EMBANKMENT SLOPE UNDER DYNAMIC LOADS,
V. M. Lyatkher, Yu. K. Zaretskii, I. N. Ivashchenko, Yu. L. Zaslavskii, and G. S. Selezney.
Hydrotechnical Construction, No 8, p 773-777, August, 1980. 3 Fig, 2 Tab. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 10-12, August, 1980.

Descriptors: *Earth dams, *Dam stability, Dam foundations, Foundation failure, *Soil mechanics, Soil properties, Earthquakes, Seismic waves, Strength, Shear stress.

In order to develop more reliable methods for evaluating the seismic stability of earth dams, it is necessary to better define the mechanical properties of the soils used in the construction of these dams. A 35-meter-high embankment with a volume of about 40,000 cubic meters was constructed within the design contour of the upstream shoulder of the Nurek dam, and experimental collapsing of the slope of the embankment under the effect of seismic shooting was carried out. The experiments were conducted using materials of the actual granulometric composition placed with the use of the established procedure of dumping and compaction used in construction. Delayed firing of several rows of explosive charges was used to form a plane wave of seismic activity. The results of this large-scale experiment showed good agreement with calculations of the stress and strain and stability of an embankment slope under the effect of seismic shooting using current methods for the determination of the characteristics of the strength of coarse fragmental soils used for the construction of critical earth structures. DYNAMIC ELASTIC AND ABSORBING PROPERTIES OF SOILS,
N. D. Krasnikov, G. S. Tolkachev, and L. A. Eisler.
Hydrotechnical Construction, Vol 15, No 5, p 279-284, May, 1981. 4 Fig, 8 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 5, p 19-22, May, 1981.

Descriptors: *Stability analysis, *Seismic properties, *Soil dynamics, Soil mechanics, Dam stability, Soil physical properties, Dynamics, Elastic properties, Earthquake engineering, Shear stress, Ultrasonics, Stress analysis, Wave propagation, Earth dams, *Hydraulic structures, Design criteria, Foundation failure, Dam foundations.

The dynamic and seismic stability of hydraulic earth structures should consider the dynamic elastic and absorbing properties of soils, which depend on density, water content, static stress state, parameters of dynamic effects, and other factors. One group of methods for determining this dependence uses high frequencies (tens of hertz to hundreds of kilohertz) and low amplitude strains (about 10 to the minus 5th power). These methods (seismic propagation, seismic well logging, ultrasonics, and longitudinal and torisonal vibrations of specimens) produce higher moduli of elasticity and lower damping coefficients than observed, leading to overestimated loads for design purposes. A second group of methods (shear apparatus, stabilometers, stress-strain analysis, and propagation of blast waves) based on lower frequencies (units to tens of hertz) and higher amplitude strains (up to 0.1) produce estimates closer to those observed. Using these values can leas to more realistic design and avoid the extra costs of overdesign. It is advisable to conduct preliminary investigations of soil properties using the first group of methods followed by application of the second group to refine the results. (Cassar-FRC)

BEARING CAPACITY OF SAND BASES (DISCUSSION OF CONSTRUCTION SPECIFICATIONS),
V. N. Dombrovskii.
Hydrotechnical Construction, Vol 15, No 8, p 488-495, 1981. 7 Fig, 15 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 38-42, August, 1981.

Descriptors: *Load distribution, *Sand, *Dam foundations, Soil mechanics, Bearing capacity, Slopes, Model studies.

Scale models were used to study the bearing capacity of sand bases for retaining structures (dams, etc.). Results of these experiments and of previous work were developed into a method for calculating the bearing capacity of sand bases for changes of angle of slope from 0 to 90 degrees. The method is usable if the founding depth does not exceed 1.5 of the width of the lower surface of a rectangular footing under an inclined load and 5.0 of the width of the lower surface under a vertical load. The ultimate load on a sand base of average or above average density for a square lower surface is 20-30% more than that of a strip, provided that the

width of the lower surface is constant and is determined by the coefficient of the slope of the lower surface. For a fixed angle of slope of the load and depth of the lower surface of the footing there is a relation between the angle of internal friction of the soil and the relative bearing capacity of the base. The ultimate load depends nonlinearly on the footing depth, which may be determined by an equation. (Cassar-FRC)

EMBANKMENT CONSTRUCTION: NEW MELONES DAM,
Army Engineers District, Sacramento, CA.
C. E. Stanage.
Journal of the Geotechnical Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No GT4, p 621-636, April, 1982. 7 Fig, 1 Tab, 1 Ref.

Descriptors: *Embankments, *Dam construction, *Construction, Soil mechanics, Earth dams, New Melones Dam, California, Rockfill dams, Geology, Dam foundations, Excavation, Grouting.

Construction of the multipurpose New Melones Dam across a canyon on the Stanislaus River, California, is described. This zoned earth and rockfill structure is 637 ft high at the maximum, 1560 ft in crest length, and 15.9 million cu yd in volume. The impervious core is inclined upstream. Details are given concerning the site geology five distinct rock groups, meta-volcanic under the dam foundation); foundation excavation, preparation, surface treatment, and grouting; embankment features, materials, and sources of materials; construction procedures for the different types of fill; and instrumentation. HYDRODYNAMIC EFFECTS IN EARTHQUAKE RESPONSE OF EMBANKMENT DAMS,
California Inst. of Tech., Pasadena.
J. F. Hall, and A. K. Chopra.
Journal of the Geotechnical Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No GT4, p 591-597, April, 1982. 5 Fig, 8 Ref.

Descriptors: *Earthquake engineering, *Dam stability, *Hydrodynamics, Soil mechanics, Earth dams.

The significance of hydrodynamic effects in the earthquake response of embankment dams was evaluated using an analytical procedure based on the substructure method. Effects of dam-fluid interaction, water compressibility, and fluid-foundation interaction were all included. Hydrodynamic effects were relatively unimportant in the response of embankment dams to horizontal ground motion because the inertia forces associated with the large mass of the dam overshadowed the small hydrodynamic pressures produced by acceleration of the dam face. The dam response to vertical ground motion was small compared with that from horizontal ground motion. (Cassar-FRC)

$12.6 M REPAIRS BILL FOR RUAHIHI CANAL.
World Water, Vol 5, No 4, p 8-9, April, 1982. 2 Fig.

Descriptors: *Canals, *Foundation failure, *Soil stability, Hydroelectric stations, Soil mechanics, Channel failure, Unstable channels, Artesian pressure, Seepage, Ruahihi Canal, New Zealand.

Repairs to the Ruhihi Canal, New Zealand, which collapsed on September 20, 1981, the day after the hydroelectric project was commissioned, will cost $12.6 million. A 1 km section of canal will be replaced by a steel or concrete pipeline. The remaining 2.35 km will be strengthened and drainage will be improved. The forebay structure, left stranded by the mishap, will be rebuilt 1 km upstream. The collapse, caused by unstable volcanic soils and artesian pressures, should have been predicted from borehole tests and knowledge of soil behavior. The insurers may refuse to honor the claim for damages because of design faults, and the Taurange Joint Generating Committee may have to look to the New Zealand government for financial help. (Cassar-FRC)

STRESS STATE OF A ROCK MASS WITH TWO PARALLEL TUNNELS WITH LOADING OF ONE OF THEM BY A UNIFORM INTERNAL PRESSURE,
R. A. Dunaevskii.
Hydrotechnical Construction, Vol 15, No 6, p 315-317, May, 1981. 1 Fig, 2 Tab, 10 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 5, p 55-57, May, 1981.

Descriptors: *Tunnels, *Stress analysis, Rock mechanics, *Hydraulic structures, Contours, Diversion structures.

When two parallel unsupported tunnels are dug to discharge water during construction of hydraulic structures, it is desirable to calculate the stresses on the walls of unloaded and loaded tunnels. This paper considers tunnels with an inverted U cross section. In the loaded tunnel stresses on the half of the contour further from the unloaded tunnel are not dependent on the distance between the centers of the tunnel. However, at the closer wall, where it joins the bottom, stresses increase markedly with decreases in distance between tunnels. When the distance between tunnel centers is greater than 6 times the radius, the effects of the second tunnel can be neglected. Stresses on the contour of the unloaded tunnel also decreases in distance between tunnels. (Cassar-FRC)

SEISMICITY IN THE MICA RESERVOIR (MCNAUGHTON LAKE) AREA: 1973-1978,
British Columbia Univ., Vancouver. Dept. of Geophysics and Astronomy.
R. M. Ellis, and B. Chandra.
Canadian Journal of Earth Sciences, Vol 18, No 11, p 1708-1716, November, 1981. 1 Tab, 6 Fig, 28 Ref.

Descriptors: *Reservoirs, *Seismology, *Earthquakes, *Dams, Stress, Seismographs, Damsites, Histograms, Faults, Geologic formations, Seasonal fluctuations, Water level, History, Geologic fractures, Structural geology. *McNaughton Lake area, *Canada.

Results of a program monitoring seismicity in the McNaughton Lake area of Canada are presented. The program began in 1973. It has located 212 earthquakes, most of which occurred in four sequences. Three sequences occurred in the Rocky Mountains near the McNaughton Lake Reservoir. The final sequence was located east of the Rocky Mountain Trench. Comparisons with historical records indicate that the seismicity pattern is similar to that of the historical record. It appears unlikely that impoundment induced the recent earthquakes. (Titus-FRC)

QUANTITATIVE RELATIONSHIP OF GROUTING TO THE REDUCTION OF GROUNDWATER FLOW THROUGH ROCK FOUNDATIONS,
Army Engineer District, St. Louis, MO.
M. J. Klosterman, T. F. Wolff, and N. G. Jahren.
Bulletin of the Association of Engineering Geologists, Vol 19, No 1, p 15-24, 1982. 7 Fig, 8 Ref.

Descriptors: *Grouting, *Seepage control, *Groundwater barriers, Rock testing, Foundation rocks, *Meramec Park Lake, *Missouri, Pumping tests, Dam foundations, Drill holes.

A test grout program was carried out at the proposed Meramec Park Lake damsite, Sullivan, Missouri. Two areas were grouted using two different methods: the modified stage-grouting method in the valley test area and the modified stop-grouting method in the upland area. Rock in the upland area was poor, with numerous small fractures. The test procedure involved pre- and post- grouting pumping tests from water wells surrounded by a 50-ft square grout curtain. After grouting, the specific capacity of the test wells was reduced by 81-97%. Considering that the bottom of the grout curtain box was open, it was determined that the grout effectively shut off groundwater flow. Optimum grout take was obtained with a mixture of 4:1 in primary and secondary holes and 6:1 in tertiary holes with addition of 2-4% bentonite. Pressures used were 1.5 psi per ft of hole depth except for the valley area, where artesian conditions required slightly higher pressures. There was no difference in grout take between AX size holes and NX size holes. Most grout injected did not spread more than 5 ft; most movement was along vertical joints rather than horizontal bedding planes. (Cassar-FRC)

CONSIDER SOIL-CEMENT FOR EROSION AND SEEPAGE CONTROL,
W. G. Dinchak.
American City and County, Vol 97, No 2, p 55-56, February, 1982.

Descriptors: *Erosion control, *Construction materials, *Cement, *Soil cement, *Linings, Soils, Erosion, Seepage, *Seepage control, Flood control, Drainage, Lagoons, Wastewater treatment, *Wastewater lagoons.

Soil-cement is a mixture of natural soils, portland cement, and water and has been used successfully as a paying material in the United States and Canada. Other uses have evolved due to its durability in exposures to sea water, domestic and industrial wastewaters, coal ash slurries, and brine solutions. Since 1965 soil-cement has been used in 25 wastewater treatment lagoons, the largest of which is in the Muskegon-Mona Lake facility in Michigan. Each of three lagoons is lined with eight inches of soil-cement. In Arizona, problems with runoff were solved by the use of soil-cement for embankment protection along arroyos. Soil-cement embankments constructed stairstep fashion also are used to protect about 6000 feet of shoreline at three villages on the north shore of the Gaspe Peninsula, Quebec, Canada. The soil-cement measures about 2.5 feet thick. A typical soil-cement mixture contains about 10% cement and 10% moisture. One particularly important property of soil-cement is its continuing strength gain after placement. High compressive strength is an important attribute when lining settling ponds and wastewater treatment lagoons. A soil-cement erosion-control facing can be placed in layers parallel to the slope. These layers also are typically about six inches in thickness. If the project includes seepage control, as in a lagoon, the bottom of the impoundment is covered with a 6 inch compacted layer of soil-cement. (Baker-FRC)

CONCRETE FOR SURFACES OF HIGH-HEAD SPILLWAYS,
L. N. Gomolko, I. S. Novikova, S. V. Sharkunov, and G. N. Tsedrov.

Group 8F—Concrete

Hydrotechnical Construction, Vol 15, No 5, p 302-307, May, 1981. 7 Fig, 1 Tab, 6 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 5, p 34-37, May, 1981.

Descriptors: *Cavitation, *Concrete mixes, *Spillways, Concrete additives, Erosion, Flow velocity, Aggregates, Ballast, Gravel.

A study of cavitation resistance of concrete showed that there was no clear-cut relationship between cavitation resistance and type of aggregate for high concrete grades. However, cavitation resistance was substantially increased by introducing additives or by reducing the water/cement ratio. Addition of sulfite yeast waste liquor (0.2% of weight of cement) increased cavitation resistance by 30-40%; hydrophobic silicone liquid (0.15%); and an epoxy compound containing diethylene glycol, by a factor of 3-5. A graph gives maximum permissible sizes of coarse aggregate as a function of flow velocity. Other graphs show the permissible height of an isolated projection for steady flow over concrete of 2 different grades. The permissible height of projections were plotted against flow velocity for ballast in concrete M300, for gravel in concrete M300, and for gravel plus ballast in concrete M400. The gravel-ballast in M400 permitted the largest projection height. These findings indicate that increased use of local gravel will reduce costs without increasing cavitation damage to concrete hydraulic structures. (Cassar-FRC)

RELAXATION IN CONCRETE,
Promon Engeharia SA, SAO Paulo (Brazil).
V. M. S. Lima, Q. M. Guedes, W. P. Andrade, and J. T. Bastos.
International Water Power and Dam Construction, Vol 33, No 12, p 27-32, December, 1981. 9 Fig, 3 Tab, 8 Ref.

Descriptors: *Concrete dams, *Creep, *Stress-strain curves, Stress analysis, Concrete technology, Mass concrete, Mathematical studies.

Concrete relaxation curves for mass concrete are usually calculated by numerical methods, using creep curves as a starting point. Details obtained from site tests of concretes used in the construction of the Tucurui and the Itumbiara hydroelectric plants in Brazil are used to assess the accuracy of three methods of calculating relaxation curves for concrete from creep data. Relaxation curves were calculated by the following three processes: numerical solution of the integral equation expressing the relaxation phenomenon; average logarithm; and Carlson's method, in which the relaxation function is determined using only the creep function plus the law of variation of the elasticity modulus with the concrete age. This analysis demonstrates that Carlson's process overestimates relaxation and that the relaxation function obtained by this process is not sufficient to preserve a strain equal to unity during the relaxation process. Application of Carlson's method demands that the creep phenomenon obeys the hypothesis used by Dischinger, which assumes parallelism of creep curves and which may not be valid. Two versions of the use of the integral equation which expresses the relaxation phenomenon are demonstrated. The first process determines the real value of relaxation through numerical solution of the integral equation. The second process, known as the average logarithm process, utilizes an alternative algorithm which leads to an entirely recurring expression. This second process results in a slight overestimation of relaxation, which diminishes as time elapses after application of the initial strain. (Carroll-FRC)

ALTERNATIVE TUNNELLING METHOD FOR RELIEF SEWER.
Civil Engineering (London), p 18, February, 1982. 1 Fig.

Descriptors: *Tunneling, *Pipelines, Unitunnel, Tunnel construction, Sewer systems, Structural settlement.

The Unitunnel system is being used to drive a sewer tunnel 280 m long and 1300 mm in diameter under and near streets and buildings in Acton, West London. The tunneling system operates like an earthworm. Frictional resistance controlled by automatically operated rubber bladders between each pipe section drives the system foward, producing a worm-like movement through the ground. When tunneling is finished, the bladders are inflated, then removed, leaving a gap which may be sealed. Work with the Unitunnel apparatus proceeds about 2.5 times faster than with a digging machine. A rate of 33 mm per min was achieved at less than full potential. No settlement was measured after the tunneling had passed under railroad tracks and within 6 ft of buildings. Only 3 mm settlement was measured in gardens where the tunneling apparatus had been operating at a depth of 10 ft. (Cassar-FRC)

WEDGE-BLOCK TUNNELS IN WATER SUPPLY,
Thames Water Authority, London, (England).
P. Cooley.
Journal of the Institution of Water Engineers and Scientists, Vol 36, No 1, p 9-26, 1982. 7 Fig, 5 Tab, 17 Ref.

Descriptors: *Tunnel linings, *Conduits, *Water supply, Water distribution, Tunnel construction, Concrete construction, Wedge block tunnels, Load distribution, Leakage, Clays, Pressure conduits, Water conveyance.

Experience in England with the wedge-block tunneling method is described in detail. This technique, first used in the 1950's, eliminates the steel lining. Concrete hoops with an open space are put in position, and a closing wedge is driven into the remaining opening. Average short-term (12 months) hoop loads were 45-67% of the overburden load. Specifications developed for constructing wedge-block tunnels are as follows: 2.54 m diameter, 140 mm ring thickness, depth of 30-57 m in London Clay, and ram thrusts of 35 tons for 0.61 m long rings and 40 tons for 0.69 m rings. Wedges have a taper of 1 in 10 at each side. Concrete molds are most suitable for casting segments. Leakage at shafts can occur, especially if the shaft is dry, because of inadequate grouting. Two wedge-block tunnels at the same level within 1-5 m of each other increased hoop loads by 7%, not enough to cause concern. (Cassar-FRC)

8G. Materials

A PIPELINE FOR ALL ENVIRONMENTS,
Stanton and Stavely, Nottingham (England).
T. R. Smith, and M. J. Sherwin.
Aqua, No 1, p 17-19, 1980.

Descriptors: *Pipes, *Iron, *Ductility, Pipelines, *Materials engineering, Environmental effects, Physical properties, *Water supply systems, Design standards.

Ductile iron pipe is capable of withstanding stresses imposed on it by climatic, topographical, geological and anthropogenic conditions. In ductile iron, which is four times stronger than grey iron, graphite is present in spheroidal form. The pipe can withstand hydraulic pressures higher than normal working pressures, a capability important where water must be moved long distances in mountainous terrain. It can tolerate very high external loadings, eliminating the need for special embedments. Pipes installed above ground need supports only every 12 meters. Excellent resistance to impact loading is important during handling and transport, excavations, water hammers, and surges. Ductile iron pipes are also fire and earthquake resistant. Flexible joints perform best in most locations-- soft ground, steep inclines, tunnels, riverbeds, and areas where excavations are common. These joints prevent damage by thermal expansion and contraction and by galvanic action. (Cassar-FRC)

THE BEHAVIOR OF ASBESTOS-CEMENT PIPE UNDER VARIOUS WATER QUALITY CONDITIONS: PART 2, THEORETICAL CONSIDERATIONS,
Environmental Protection Agency, Cincinnati, OH. Drinking Water Research Div.
M. R. Schock, and R. W. Buelow.
Journal of the American Water Works Association, Vol 73, No 12, p 636-651, December, 1981. 27 Fig, 11 Tab, 91 Ref.

Descriptors: *Asbestos cement, *Corrosion control, Water distribution, Pipes, Zinc compounds, Acidic water, coatings, solubility, Water quality, Calcium carbonate, *Pipelines, Chemistry precipitation, Rehabilitation.

Several conclusions were made in a study of the reaction of asbestos cement pipe with water containing various constituents. (1) The traditional agressiveness index based on calcite saturation is inadequate to describe the degradation of asbestos cement pipe. The presence of naturally-occurring protective materials, pH, carbonates, calcium, disinfectant concentrations, temperature, and organic matter must also be considered. (2) Some materials cause pipe matrix dissolution but do not necessarily release asbestos fibers. (3) The chloride, sulfate, and orthophosphate salts of zinc are satifactory corrosion inhibitors for asbestos cement pipe at the proper concentrations and pH. The mechanism involves formation of a zinc hydroxy carbonate precipitate which reacts with the pipe surface to form a harder zinc silicate coating. (4) Tthe Zn orthophosphate protects against corrosion in a metal-asbestos cement pipe system through the action of the orthophosphate rather than Zn. Zinc chloride and sulfate are not effective in these situations. (5) A degraded asbestos cement pipe with loose fibers cannot be readily rehabilitated by Zn treatment. (6) Results of Zn solubility modeling presented in this paper are also applicable to studies of new galvanized piping. (Cassar-FRC)

USE OF WATERTIGHT FILM FACINGS FOR REPAIR WORKS ON THE GREAT STAVROPOL CANAL,
Y. U. Baigorov, Y. M. Kosichenko, and B. I. Sergeev.
Hydrotechnical Construction, Vol 15, No 6, p 369-373, June, 1981. 5 Fig, 1 Tab, 5 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 6, p 40-43, June, 1981.

Descriptors: *Seepage control, *Canal linings, Canal seepage, Polymers, Plastics, Maintenance, *Great Stavropol Canal, *USSR.

Seepage control measures at the Great Stavropol Canal in the North Caucasus were necessary because serious problems were observed during 1965-1979. Deformations, intense local seepage, threat of break-through, and rise in groundwater levels were caused by complex relief of the canal route, susceptibility of soils to subsidence and piping, absence of watertight facings, insufficient compaction of soil, and poor construction techniques. Small-scale installation of a soil-plastic film facing showed that the specific drainage flow in the section was reduced 17-30%. Installation of the soil-film facings involved stopping the streamflow in the construction area with cofferdams, excavating

a meter-thick soil layer, compacting the base, filling with high quality soil, laying butyl rubber film of 1.5 - 3 mm thickness, adding a protective layer of loam, and finishing with a protective gravel-rubble layer. (Cassar-FRC)

GALVANIZED STEEL STALLS TREATMENT PLANT CORROSION,
B. Harmon.
Water/Engineering and Management, Vol 129, No 2, p 42-43, February, 1982. 3 Fig.

Descriptors: *Wastewater facilities, *Corrosion, Zinc, *Galvanized steel, Construction, *Design criteria, Secondary wastewater treatment, Wastewater treatment, *Baltimore, Maryland.

The majority of the major structures and components of the Baltimore Back River Wastewater Treatment Plant have been virtually maintenance-free for over 30 years, largely due to the extensive use of hot dip galvanizing with zinc. The plant was constructed in 1911 and functions as a secondary treatment facility, occupying a 453 acre wooded site in eastern Baltimore County at the head of the Back River. Back River has three levels of treatment. The preliminary step includes bar screens and grit removal basins. Screening removes large floating objects which may clog or damage pipes, pumps or other devices. The grit removal basin is the next stage; here, the stream velocity is reduced and granular particles settle out. The wastewater is then conveyed to the primary tanks where smaller suspended organic particles settle in seven large sedimentation basins. About 30-50% of the suspended organic material normally settles and is removed as sludge. Secondary treatment is then accomplished by trickling filters and activated sludge. The sludge process uses aerobic microorganisms to feed on suspended organic material for growth and reproduction. Applications of the zinc-coated steel exposed to atmospheric corrosion are centered around the aeration process. Much of the structural steel, especially at the water line, is galvanized, as are the scum and flow troughts in the final settling tanks. Galvanized steel is prepared by immersing a precleaned fabricated part or structure into a kettle of molten zinc at a temperature of about 850 degrees F. The steel remains in the zinc bath until its temperature rises to that of the zinc. As the object is removed, a protective coating of zinc is bonded to the steel. (Baker-FRC)

THE BOOMING BUSINESS IN WICK DRAINS,
A. Morrison.
Civil Engineering (New York), Vol 53, No 3, p 47-51, March, 1982. 1 Fig.

Descriptors: *Drainage, *Dewatering, *Wick drains, Soil consolidation, Sand, Permeability.

Wick drains, introduced into the U.S. in 1978, have been replacing sand drains for soil consolidation. The Kjellman wick, invented before World War II in Sweden, consisted of three layers of cardboard, the inner one containing ten channels. Modern wick drains have many more channels than the original invention. Polyester or paper filters offer high permeability, wet strength, and shear resistance. Installation to 100 ft is possible. Most can be installed using a conventional vibrating hammer with a wick installation rig. Prices range from $0.70 to $1.20 per foot of drain installed compared to $3.50 to $6.50 per foot of sand drains. Five suppliers serve the U.S. with different types of products--paper or polyester filters, different permeabilities, and different drain capacities. Installation methods must consider the sensitivity of the soil. Suppliers and literature on wick drains are listed. (Cassar-FRC)
W82-05192

CASE STUDY OF PREDICTION OF SULFIDE GENERATION AND CORROSION IN SEWERS,
Brown and Caldwell, Sacramento, CA.
W. J. Meyer.
Journal of the Water Pollution Control Federation, Vol 52, No 11, p 2666-2674, November, 1980. 3 Fig, 6 Tab, 5 Ref.

Descriptors: *Sulfides, *Corrosion, *Liners, Pipes, Concrete, Construction materials, Corrosion control, Wastewater treatment, *Sewer systems, Design criteria, Construction, *Case studies, *Sacramento, California.

A case study was performed to compare the results predicted by sulfide generation and corrosion equations with observed conditions in the Central Trunk sewers located in Sacramento County, California. Data have been accumulated on this trunk system by the county since the trunk was placed into operation in 1962. The Central Trunk serves the southeastern portion of the Sacramento metropolitan area. The sewer conveys both domestic and industrial wastewater from its tributary area and solids from the Northeast and Cordova wastewater treatment plants. No correlation was found between the measured and predicted sulfides using Thistlethwayte's equations. These equations result in sulfide predictions which are much higher than those observed. The sulfide buildup predicted by Pomeroy's equations assuming a less-conservative coefficient for sulfide losses of 0.96 correlates well with measured sulfide concentrations. The change in sulfide conditions occurring at major junctions should be considered when the characteristics of the wastewater in the tributary sewers vary significantly from the wastewater characteristic in the primary interceptor. Use of the Pomeroy equations for predicting sulfide generation and resultant corrosion provides a useful tool in the design of sewers. The designer has several options to assure an adequate service life: using acid-resistant materials, providing oxygen or other oxidant to the wastewater, adding chemical control of sulfide generation, providing sacrificial concrete covers over the reinforcing steel and/or using calcareous aggregate, using protective liners on the pipe and structures, or designing system hydraulics to avoid sulfide generation. (Baker-FRC)

GUIDEVANE EROSION AT MAO TIAO HE,
L. Xue-Zhong.
International Water Power and Dam Construction, Vol 34, No 2, p 23-26, February, 1982. 4 Fig.

Descriptors: *Powerplants, *Corrosion, Mao Tiao He river, China, Design criteria, Abrasion, Sand, Turbines, Cavitation, Pumps.

Unusual and severe wear erosion was experienced by the guidevanes of Unit II at the Fourth Stage power station on the Mao Tiao He river in China. The powerhouse of the station contains three Francis turbines operating under a net head of 53-65 meters and a draft head of -3.5 meters. Unit II went into operation in September of 1971. In March 1973 severe wear erosion caused by sand in the flow was found on all of the guidevanes. No similar damage was noted on the surfaces of other parts such as the spiral case, the stayvane and the runner. During the station's operation, Units II and III had each worked about 5000 hr, including about 500 hr of operation as condensers. The upper part of the inside of the casing of all guidevanes had suffered severe wear, affecting between a third and half of the inside area in the form of two wide, smooth horizontal grooves. No typical trace of cavitation erosion was noted in the wear area. The wear erosion only appeared on the upper part of the inside of the guidevanes. In Unit III under similar operating conditions, no such wear was found. The problem could not be traced to turbine wear through sand flow, although the worn surfaces appeared to be features of sand wear erosion. In studies of the water movement, the wearing was traced to the water in the runner chamber not being under pressure and the runner turning under the water during this operating condition. When a turbine operates as a pump, when idling, the sand carried by the water in the draft tube gradually accumulates in the corner formed by the protective plate and the upper part of the inside of the guidevanes. A circular space is created where the sand concentration increases according to the operating time, causing severe wear on the guidevanes. (Baker-FRC)

LOAD FACTORS AND NON-DESTRUCTIVE TESTING OF CLAY PIPE,
National Clay Pipe Inst., Crystal Lake, IL.
E. J. Sikora.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2964-2976, December, 1980. 16 Fig, 1 Tab.

Descriptors: *Sewer systems, *Load factors, *Pipes, Nondestructive tests, Clay pipe, Bedding materials, Backfill, Trenches, Sand, Compaction, Soil compaction, Gravel, Flooding, Materials testing.

Nondestructive tests were conducted to determine the validity of load factors presently used in design of sewer systems with vitrified clay pipe. The current load factors for Classes B, C, and D bedding systems were found valid when stable bedding materials were used. The best all around choice of bedding material is a 19.2-6.3 mm gradation. Bedding materials of sizes 6,7, and 8 and combinations thereof are all capable of developing the required load factors. The load factor and quality of installation in Class B (except for sand) and Classes C and D are improved by shovel-slicing the bedding material under the pipe haunches. Stability of a bedding material increases with increasing particle size, but mixtures with particles larger than 19 mm are difficult to shovel-slice. Angular, well graded bedding materials are desirable in trenches with irregular bottoms or with difficult-to-maintain widths and in all Class B installations. Use of rounded bedding material is permissible in narrow trenches where bedding is confined. Although sand has performed well as a bedding material in all-sand regions (deltas and coastal areas) it should not be imported for this use because of its variable performance, especially under flooding conditions. MEASURING RESERVOIR GROUND MOVEMENTS,
Nottingham Univ. (England).
V. Ashkenazi, A. H. Dodson, D. E. B. Jones, and N. Samson.
Civil Engineering (London), p 35,37,39, 41-43, February, 1982. 3 Fig, 3 Tab, 4 Ref.

Descriptors: *Reservoirs, *Surveying instruments, *Dam stability, Thames Water Authority, Queen Mother Reservoir, Dachet, *England, Embankments, Earthworks, Subsidence, Networks, Network design.

A geodetic surface reference system installed at the Queen Mother Reservoir, Dachet, England, accurately measured horizontal and vertical surface movements. The network consisted of 10 station pillars on the downstream crest, two remote pillars, a 700 m distant benchmark, and 64 detail points around the toe of the embankment. Angles were measured with a Wild T2 theodolite and distances with a Wild D 13S Distomat. Measurements over a 2-year period indicated that the embankment crest moved 15 mm outward and 12 mm downward during this time. (Cassar-FRC)

8H. Rapid Excavation

TUNNELLING MACHINE SAVES TIME AND MONEY,
International Water Power and Dam Construction, Vol 33, No 12, p 47-49, December, 1981. 1 Fig, 2 Tab.

Descriptors: *Water conveyance, *Tunneling, *Construction equipment, Rapid excavation, Mountains, Austria, Rock excavation.

An Atlas Copco Jarva tunnel boring machine is being used in the construction of the Wolla water tunnel in Karnten, Austria. The tunnel, which will

be 6.7 kilometers long and 3.5 meters in diameter, is part of a large hydroelecric complex in Karnten. Ten 11 hour shifts were required for assembly of the machine at the tunnel entrance. Atlas Copco provided two specialists during assembly, two for training, and one throughout the tunneling period. Conventional drill and blast procedures were used to excavate the first 135 meters of the tunnel, since this section was too narrow for the machine to bore and the rock was not suitable. The machine is generally able to work its way through the alpine gneiss and mica schists at an average rate of about 32.7 meters per 22-hour day. The tunnel boring machine is equipped with a roof shield for protection from falling rock, but the removal process required when overbreak falls below and beneath the machine is time-consuming. The cutters, also manufactured by Atlas Copco, usually last for bout 25 meters of tunnel. Use of the tunnel boring machine is resulting in savings of up to 50% in time and labor, 50% in energy, and 10% in costs in comparison with the estimated costs associated with using conventional drill and blast methods to create this tunnel. The tunnel boring machine also produces a smooth surface and regular shape. (Carroll-FRC)

EXPERIENCE IN PREPARING THE ROCK FOUNDATION OF THE DNESTR HYDROELECTRIC STATION,
A. E. Azarkovich, M. I. Shuifer, A. I. Tsvetkov, S. S. Gandzyuk, and E. L. Budnikov.
Hydrotechnical Construction, Vol 15, No 8, p 459-461, 1981. 1 Fig, 2 Tab, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 21-22, August, 1981.

Descriptors: *Explosives, *Foundation rocks, *Excavation, Blasting, Rock foundations, Dam foundations, Hydroelectric plants, Drilling, Dnestr Hydroelectric Station.

The Dnestr hydrostation foundation was prepared without jackhammer drilling at a labor reduction of 0.33 man days per sq m of foundation. Formerly, cracks in the rock foundations were avoided by removing the last rock layer in the following manner: a 4-5 m layer was removed by firing 0.11 m diameter long-hole charges in a close pattern, the next 1 m loosened by 1 m short-hole charges to a depth of 0.6 m, and the remaining 0.4 m removed manually by picks and wedges. The new scheme used long-hole charges of 0.15 m diameter arranged in the normal pattern for the upper 3-4 m layer. The lower 2 m was loosened by close spaced long-hole charges of the calculated diameter (in this case 0.085 m) in 0.11 m diameter boreholes. Little manual excavation was required after loosening rocks in this manner. Testing showed that the rock foundation quality was within specifications. (Cassar-FRC)

DRIVING LARGE HYDRAULIC TUNNELS BY THE STEPPED FACE METHOD,
V. M. Mostkov.
Hydrotechnical Construction, Vol 15, No 8, p 496-502, 1981. 3 Fig, 2 Tab, 8 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo. No 8, p 47-51, August, 1981.

Descriptors: *Tunneling, *Hydraulic structures, *Excavation, Tunnel construction, Stepped face method.

The stepped-face method for excavating tunnels of large cross section involves dividing the tunnel into two to four levels, each 4-7 m high, and excavating each level at a 30-50 m lag behind the next higher level. This produces a stepped face which allows trucks, bulldozers, and cranes to move up or down a 20-25 degree blasted rock slope. Blasting and excavation proceed simultaneously on each step. This method is suitable for tunnels more than 10 m high in comparatively homogeneous rocks. The tunnel roof and walls are supported on each level by anchors and shotcrete. Concreting is done with a lag behind digging or after completion. A typical three-level tunnel will advance 2.5-3.5 m per day, about 1.5 times faster than with the lower bench method. (Cassar-FRC)
W82-05586

QUALITY OF CONTOURING WORKINGS WHEN DRIVING UNDERGROUND STRUCTURES AT THE NUREK HYDROSTATION,
M. D. Bondarenko.
Hydrotechnical Construction, Vol 15, No 8, p 453-458, 1981. 3 Fig, 5 Tab, 3 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 8, p 17-20, August, 1981.

Descriptors: *Underground structures, *Tunnel construction, *Rock excavation, Tunneling, Tunnel linings, Quality control, Excavation, Blasting.

Graphs were prepared to determine the average linear overbreak of tunnels under construction for comparison with standards or regulations. Two graphs were constructed: one as a function of the specific perimeter of the tunnel and overbreak coefficient and the other as a function of the thickness of the concrete lining and overplacement coefficient. These were applied to an analysis of the quality of tunneling at the Nurek hydrostation, USSR. Average linear overbreak was 0.46 m, of which overbreak due to boring accounted for 0.22 m and overbreak due to geological factors accounted for 0.24 m. Tunneling quality is affected by two main factors: boring and blasting methods and structural geology of the rock mass. (Cassar-FRC)

ENGINEERING ASPECTS OF FISH PROTECTION AT WATER INTAKES,
B. S. Malevanchik.
Hydrotechnical Construction, Vol 15, No 6, p 374-381, June, 1981. 6 Fig, 1 Tab, 9 Ref. Translated from Gidroteknicheskoe Stroitel'stvo, No 6, p 44-48, June, 1981.

Descriptors: *Fish guiding, *Protection, *Intakes, Fish barriers, Fish conservation, Diversion structures, Hydroelectric plants, Reservoirs, Headrace, Screens, Meanders, Canals, Fish eggs.

Three methods of protecting fish from entering water intakes of large hydroelectric installations are presently under research in the Soviet Union. Fish barriers, which retain the eggs and young fry on screens or shields, are labor intensive and not too effective in protecting fish at a large intake. Fish-enclosing methods withdraw intake water from boom-enclosed areas outside of fish habitats. During migration the water intake can be stopped or reduced to a safe level. However, enclosures are only effective when the fish distribution (diurnal and seasonal, vertical and horizontal) has been thoroughly documented for the individual water body. Fish diverting methods concentrate the drifting fry population into a narrow band along one of the stream banks and divert the flow into an area unaffected by the water intake. Studies of fish in meandering streams and in test flumes show that the fish movement obeys the laws of fluid motion. Maximum concentration of fry is near the concave bank of the stream where the transverse velocity component changes direction from the concave to the convex bank. A 7 degree bottom slope toward the concave bank intensifies the fish-concentrating effect. A curved headrace is of canal curvature/canal width of 3 to 5 and a 7-10 degree slope toward the convex bank. The second most important element is a fish diversion structure one third to one fifth the depth of water in the canal. Optimum water velocity in the headworks is 1.2-1.5 times greater than in the headrace. (Cassar-FRC)

PREDICTIVE MODELS OF BENTHIC MACROINVERTEBRATE DENSITY FOR USE IN INSTREAM FLOW STUDIES AND REGULATED FLOW MANAGEMENT,
Wyoming Univ., Laramie. Water Resources Research Inst.
J. A. Gore, and R. D. Judy, Jr.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 11, p 1363-1370, November, 1981. 10 Fig, 3 Tab, 24 Ref.

Descriptors: *Stream fisheries, *Mathematical models, *Population density, *Macroinvertebrates, Prediction, Benthic fauna, Instream flow, *Regulated flow, Flow control, Aquatic insects, Mathematical equations, Computer models, Simulation analysis, Fish food, Water management.

If a streamflow management strategy is to assure optimum fish production, it must include a flow to maintain invertebrates, which are often the primary source of food for fish. The U.S. Fish and Wildlife Service, Cooperative Instream Flow Service Group, has developed the PHABSIM model, an incremental method for the determination of habitat suitability for sport fish species at various discharge levels. A similar method for determining optimum conditions for stream macroinvertebrates is proposed as an adjunct to the Fish and Wildlife Service model. This proposed method stresses predictions of density maxima and flow predictions for maintenance of suitable lotic habitat. The PHABSIM model was used to determine velocity, depth, and substrate preferenda for 19 aquatic invertebrates. The curve-fitting equations of the PHABSIM computer simulation showed high reliability in predicting physical habitat tolerance of selected aquatic insects. An example using Nectopsyche lahontonensis is presented. The new predictive model, which utilizes exponential polynominal analysis, provides a 'fine-tuning' function to allow a narrower confidence limit on regulated flow recommendations. This model also responds to criticisms of earlier models which do not include the dependence of velocity and depth in stream channel hydraulics. The added cross-product term in the model alters the predicted peak responses (density) with random changes in depth and velocity. The effectiveness of this model in stream management has not yet been tested. (Carroll-FRC)

PLACER MINING AND SALMON SPAWNING IN AMERICAN RIVER BASIN, CALIFORNIA,
Bureau of Reclamation, Sacramento, CA.
N. P. Prokopovich, and K. A. Nitzberg.
Bulletin of the Association of Engineering Geologists, Vol 19, No 1, p 67-76, 1982. 7 Fig, 2 Tab, 17 Ref.

Descriptors: *Spawning, Aquatic habitats, Stream beds, *American River, *California, *Salmon, Fish, *Mine wastes, *Dredging, Tailings, Spoil banks, Gravel, Gold, Channel improvement, Geology, Petrography, Alluvial deposits, *Water pollution effects.

The American River, near Sacramento, California, was apparently improved as a salmon spawning stream as the result of gold mine dredging operations. A 70 sq km tailing area, one of the largest in the state, is located on this river. Gold dredges appeared in California in the 1900's, and draglines were introduced in the 1930's. 1308 pebbles in 12 gravel-rich sites favorable for salmon spawning were examined by hand lens and classified into four groups: metamorphic, granitic, volcanic, and quartz. At five sites the pebble composition reflected the composition expected from upstream rocks. At five other sites the gravel composition was similar to that of the dredge tailings rather than the average composition of the water-shed or the average composition of rocks in the main and tributary canyons. Although no reliable data on pre- and post-dredging spawning conditions in the American River are available, some scientists feel that present-day spawning conditions are better than in pre-dredge times. (Cassar-FRC)

FISHERY IMPORTANCE OF THE URAL-CASPIAN FISHING DISTRICT AND PROBLEMS OF ITS WATER SUPPLY,
A. P. Musatov, and Y. N. Podushko.
Water Resources, Vol 8, No 2, p 132-135, March-April, 1981. 5 Ref. Translated from Vodnye Resursy, No 2, p 72-76, March-April, 1981.

Descriptors: *Fisheries, *Water management, *Water transfer, Sturgeon, Caspian Sea, *Ural River, Volga River, Canals, Spawning, Reservoirs, Lake Chelkar, Water resources development, Runoff, *USSR.

The effect of water management of the Ural River on sturgeon spawning is discussed. Sufficient flooding of the spawning grounds (total of 1700 ha) occurs when spring runoff exceeds 5 cu km per year. If the region between the Ural and the Volga is developed for grain farming and animal husbandry, water consumption will increase. This will produce annual runoffs less than 5 cu km in 17 to 30 years. Of these 17 years, 11 will have flows less than 3 cu km. During 1936-66 annual runoff was less than 5 cu km only six times. The authors believe that the discharge volume of the Ural can be maintained at amounts optimal for fish reproduction only by delivering Volga water to the Ural. A planned 425 km canal can supply enough water to meet fishery requirements. The necessary increase in regulating storage could be provided by using Lake Chelkar on the Ural banks to receive water from the proposed canal and deliver it to the Ural via the Solyanka River. An increase of 5 m in embankment height would provide a total of 2.5 cu km storage. This would permit annual Ural runoff of 75% and 50% probabilities of 7 and 10 cu km, annual runoff, respectively, assuring optimal conditions for reproduction and foraging of sturgeons and semimigratory fish in the eastern part of North Caspian Sea. W82-04790 5F

The Effect of Sulfate on Aluminum Concentrations in Natural Waters: Some Stability Relations in the System Al2O3-SO3-H2O at 298 K,
W82-05581 2K

AMAZON RIVER
Plankton Metabolism and Carbon Processes in the Amazon River, Its Tributaries, and Floodplain Waters, Peru-Brazil, May-June 1977,
W82-05197 2K

AMERICAN RIVER
Placer Mining and Salmon Spawning in American River Basin, California,
W82-05200 8I

AMMONIA
Criteria for Nitrification in Fixed Film Reactors,
W82-05352 5D

Effect of Turbulent Dispersion on the Rate of Ammonia Nitrogen in Rivers,
W82-05418 5B

Investigations of Natural Hungarian Zeolite for Ammonia Removal,
W82-05482 5D

AMMONIUM
Ammonium Uptake by Micronesian Species of Gracilaria (Rhodophyta),
W82-05311 5G

ANABAENA
Bioassays and the Algal Populations of Hastings Lake, Alberta, Canada,
W82-05484 2H

ANAEROBIC CONDITIONS
Anaerobic Treatment in Novel Contact Digester,
W82-05681 5D

Role of Surface Active Media in Anaerobic Filters,
W82-05816 5D

ANAEROBIC DIGESTION
Package Anaerobic Sludge Digestion.
W82-04850 5D

Anaerobic Treatment of High-Strength Wastes,
W82-04907 5D

Influence of Temperature on the Anaerobic Acidification of Glucose in a Mixed Culture Forming Part of a Two-Stage Digestion Process,
W82-05240 5D

Microbial Ecosystems Responsible for Anaerobic Digestion and Composting,
W82-05252 5E

Use of Bench-Scale Digesters to Evaluate Full-Scale Digester Performance,
W82-05272 5D

ANAEROBIC DIGESTION

pH Influence on Acidogenic Dissimilation of Glucose in an Anaerobic Digestor,
W82-05341 5D

Energy Conservation and Alternative Energy Sources in Wastewater Treatment,
W82-05440 5D

ANALYTICAL TECHNIQUES
Continuous Measurements of Dissolved Oxygen in Water Culture by a Self-Calibrating Monitor,
W82-05015 7B

ANCHORAGE
Hydrogeology for Land-Use Planning: The Potter Creek Area, Anchorage, Alaska,
W82-04981 5G

ANIMAL WASTES
Water Quality in a Stream Receiving Dairy Feedlot Effluent,
W82-04860 5B

An Evaluation System to Rate Feedlot Pollution Potential,
W82-05207 5B

Agricultural Runoff and Water Pollution,
W82-05569 5B

ANODIC STRIPPING VOLTAMMETRY
Anodic Stripping Voltammetry as an Analytical Tool,
W82-04811 5A

ANTARCTICA
A Mechanism for the formation of Large Icebergs,
W82-04798 2C

The Microfauna of Algal Mats and Artificial Substrates in Southern Victoria Land Lakes of Antarctica,
W82-05096 2H

ANTIBODIES
Enzymes and Antibodies as Sensors of Toxic Substances,
W82-05160 5A

ANTIMONY
Determination of Arsenic and Antimony in Water and Soil by Hydride Generation and Atomic Absorption Spectroscopy,
W82-05141 5A

Sample Digestion Procedures for Simultaneous Determination of Arsenic, Antimony, and Selenium by Inductively Coupled Argon Plasma Emission Spectrometry with Hydride Generation,
W82-05360 5A

AQUATIC BACTERIA
Biodegradation of Synthetic Crude Oil in Two Rivers of Northern Alberta, Canada,
W82-05486 5B

AQUATIC ENVIRONMENT
Biological Monitoring of Hazardous Wastes in Aquatic Systems,
W82-05154 5A

Relationship Between the Distribution of Phosphorus Compounds in the Tissues of the Bivalve Anodonta Cygnea and Environmental Phosphorus Level,
W82-05506 5C

AQUATIC FAUNA
The Microfauna of Algal Mats and Artificial Substrates in Southern Victoria Land Lakes of Antarctica,
W82-05096 2H

AQUATIC HABITANTS
The Impact of Managed Streamside Timber Removal on Cutthroat Trout and the Stream Ecosystem,
W82-05538 5C

AQUATIC HABITATS
Pesticide Effects on Aquatic Habitats,
W82-05146 5C

AQUATIC LIFE
Overview and Assessment of Biological Sensing,
W82-05156 5C

New In-Situ Techniques in Biomonitoring,
W82-05157 5A

The Ecological Case for the Creation of the Danube-Dnieper Water Resources Utilization System,
W82-05329 6G

Manganese, Zinc and Copper in Hydrobionts in the Danube and the Northwestern Black Sea,
W82-05458 5B

Biological Responses on Lakes in the Mount St. Helens Blast Zone,
W82-05519 5C

AQUATIC PLANTS
On the Determination of the Degree of Weedage in Flowing Waters (Zur Ansprache Des 'Verkrautungszustandes' in Fliess-Gewassern),
W82-05092 7B

Diel Variations of Certain Physico-Chemical Parameters of Water in Selected Aquatic Systems,
W82-05097 2H

Water Fluctuation and the Aquatic Flora of Lake Miccosukee,
W82-05808 4A

AQUATIC WEED CONTROL
The Utilization of Grass Carp, Ctenopharyngodon Idella Val., for Hydrilla Control in Lake Baldwin, Florida,
W82-05274 4A

AQUIA AQUIFER
Map Showing the Potentiometric Surface of the Aquia Aquifer, May 19-23, 1980,
W82-04978 7C

AQUIFER CHARACTERISTICS
Groundwater Resources of the Williamsport Region, Lycoming County, Pennsylvania,
W82-04971 2F

Groundwater and Geology of the Cumberland Valley, Cumberland County, Pennsylvania,
W82-04972 2F

Groundwater Resources of the Gettysburg and Hammer Creek Formations, Southeastern Pennsylvania,
W82-04973 2F

Assessment of a Regional Aquifer in Central Illinois,
W82-05052 2F

Bedrock Aquifers in the Lower Dirty Devil River Basin Area, Utah, with Special Emphasis on the Navajo Sandstone,
W82-05220 7C

Results of Deep-Well Injection Testing at Mulberry, Florida,
W82-05224 5B

Numerical Simulation of a Thick Freshwater Lens: Pearl Harbor Groundwater Model,
W82-05621 2F

Determination of Aquifer Parameters Using Regression Analysis,
W82-05734 2F

The Hydrogeological Basis for a Water Supply to Kabwe, Zambia,
W82-05804 4B

Hydrogeologic Reconnaissance of the Republican River Basin in Nebraska,
W82-05828 7C

Ground-Water Reconnaissance of Part of the Lower Kenai Peninsula, Alaska,
W82-05837 2F

AQUIFER MANAGEMENT
Aquifer Management in Dade County,
W82-05784 5G

AQUIFERS
Map Showing the Potentiometric Surface of the Aquia Aquifer, May 19-23, 1980,
W82-04978 7C

Compilation of Hydrologic Data for the Edwards Aquifer, San Antonio Area, Texas, 1934-79.
W82-04987 7C

Assessment of a Regional Aquifer in Central Illinois,
W82-05052 2F

Test-Hole Data for the Edwards Aquifer in the San Antonio Area, Texas,
W82-05218 7C

Bedrock Aquifers in the Lower Dirty Devil River Basin Area, Utah, with Special Emphasis on the Navajo Sandstone,
W82-05220 7C

Quality of Ground Water in Routt County, Northwestern Colorado,
W82-05227 2F

Stream-Aquifer Influence Coefficients as Tools for Simulation and Management,
W82-05346 2F

Groundwater Strategy: Protecting a Vital Resource,
W82-05403 5B

Radium Content and the 226Ra/228Ra Activity Ratio in Groundwater from Bedrock,
W82-05450 2K

Groundwater Resources of Kwajalein Island, Marshall Islands,
W82-05546 4B

Tracing Interaquifer Connections in the Kefar Uriyya-Agur Region (Israel), Using Natural Uranium Isotopes,
W82-05644 2F

Evidence for a Shallow Highly-Permeable Zone in the Chalk of Hampshire, U.K.,
W82-05645 2F

Cape Cod Aquifer, Cape Cod, Massachusetts,
W82-05807 2F

Chloride and Total Hardness Concentrations of Water From the Upper Part of the Floridan Aquifer in St. Johns County, Florida,
W82-05829 7C

Hydrogeologic Sections Through Lee County and Adjacent Areas of Hendry and Collier Counties, Florida,
W82-05830 7C

Map Showing how the Potentiometric Surface of the Magothy Aquifer of August 1980 Differed from the Potentiometric Surface of September 1977, in Southern Maryland,
W82-05838 7C

Potentiometric Surface of the Floridan Aquifer, Southwest Florida Water Management District, September 1981,
W82-05840 7C

Potentiometric Surface of the Floridan Aquifer in the St. Johns River Water Management District and Vicinity, Florida, September 1981,
W82-05849 7C

Potentiometric Surface of the Floridan Aquifer in Central Sumter County, Florida, September 1981,
W82-05850 7C

ARCH DAMS
Stress-Strain State of an Arch Dam Based on Data of Long-Term On-Site Observations,
W82-05112 8A

ARCTIC
Evaporation at a High Arctic Site,
W82-04899 2D

ARGENTINA
Issues in Simulation Model Design--A Case Study,
W82-05627 4A

ARIZONA
Nitrogen and Phosphorus Dynamics in Hot Desert Streams of Southwestern U.S.A.,
W82-04930 2K

Arizona Ground-Water Reform: Innovations in State Water Policy,
W82-04933 6E

Reconnaissance Samplings and Characterization of Aquatic Humic Substances at the Yuma Desalting Test Facility, Arizona,
W82-04983 3A

Maps Showing Ground-Water Conditions in the San Simon Wash Area, Papago Indian Reservation, Arizona--1979,
W82-05231 7C

Maps Showing Ground-Water Conditions in the Agua Fria Area, Yavapai and Maricopa Counties, Arizona-1979,
W82-05232 7C

Rapid-Infiltration Research at Flushing Meadows Project, Arizona,
W82-05334 5D

Annual Summary of Ground-Water Conditions in Arizona, Spring 1979 to Spring 1980.
W82-05826 4B

Map Showing Ground-Water Conditions in the Sacramento Valley Area, Mohave County, Arizona--1979,
W82-05827 7C

ARKANSAS
Discharge Data at Water-Quality Monitoring Stations in Arkansas, 1980 Water Year,
W82-05841 7C

AROMATIC COMPOUNDS
Analysis of Marine Sediment, Water and Biota for Selected Organic Pollutants,
W82-04823 5A

Microbial Degradation of 14C-Diphenylamine in a Laboratory Model Sewage Sludge System,
W82-04832 5D

Polycyclic Aromatic Hydrocarbons in Sediments and Associated Benthos in Lake Erie,
W82-04882 5A

Biosorption of Hydrophobic Organic Pollutants by Mixed Microbial Populations,
W82-04885 5B

Direct Analytical Method for Aromatic Compounds in Water by Steam Carrier Gas Chromatography,
W82-05164 5A

AROMATIC HYDROCARBONS
Photolysis of Polycyclic Aromatic Hydrocarbons in Water,
W82-04835 5B

ARSENIC
Determination of Arsenic and Antimony in Water and Soil by Hydride Generation and Atomic Absorption Spectroscopy,
W82-05141 5A

Fingerprinting Inorganic Arsenic and Organoarsenic Compounds in the Situ Oil Shale Retort and Process Waters Using a Liquid Chromatograph Coupled with an Atomic Absorption Spectrometer as a Detector,
W82-05151 5A

Sample Digestion Procedures for Simultaneous Determination of Arsenic, Antimony, and Selenium by Inductively Coupled Argon Plasma Emission Spectrometry with Hydride Generation,
W82-05360 5A

Trace Determination of As(III) and As(V) in Natural Waters by Differential Pulse Anodic Stripping Voltammetry,
W82-05580 5A

ASBESTOS CEMENT
The Behavior of Asbestos-Cement Pipe under Various Water Quality Conditions: Part 2, Theoretical Considerations,
W82-04791 8G

ASPHALT
Investigating Potential Water Contamination by Petroleum-Asphalt Coatings in Ductile-Iron Pipe,
W82-05676 5A

ASPHALT CONCRETE
Design of the Composition of Transition Layers of Asphaltic Concrete Membranes in Earth Dams,
W82-05113 8A

ASSESSMENTS
Family Life Cycle Disruption in Rural Communities: The Case of the Lake Shelbyville Reservoir,
W82-04966 4C

Water Quality Planning in the Northeast and Midwest: The Section 208 Experience,
W82-05315 6B

ASSIMILATIVE CAPACITY
A Consistent Methodology for Wasteload Allocations,
W82-05702 5G

ASSINIBOINE RIVER
Flood Control and Flow Regulation Problems on the Assiniboine River,
W82-05389 4A

ATMOSPHERIC PRECIPITATION
Identification of Independent Rainstorms,
W82-05708 2B

ATMOSPHERIC PRESSURE
The Effect of Pressure on the Solubility of Minerals in Water and Seawater,
W82-05135 1B

ATMOSPHERIC WATER
Moisture Analysis from Radiosonde and Microwave Spectrometer Data,
W82-04900 2B

Atmospheric Moisture Transport and the Water Balance of the Mediterranean Sea,
W82-05050 2A

ATOMIC ABSORPTION SPECTROSCOPY
A Simple and Rapid Method for the Determination of Lead and Cadmium in Sediment by Graphite Furnace Atomic Absorption Spectrometry,
W82-05020 5A

ATTITUDES
Local Attitudes Toward Alternative Uses of a Reservoir Project,
W82-05743 6B

Water Management in the Maritimes,
W82-05776 6B

AUSTRALIA
Downstream Reduction of Rural Channel Size with Contrasting Urban Effects in Small Coastal Streams of Southeastern Australia,
W82-04862 2E

On the Chemistry and Biota of Some Saline Lakes in Western Australia,
W82-04940 2H

The Ecology of Plankton Fauna in Saline River Pools,
W82-04941 2L

The Limnology of Saline Lakes in Western Victoria, A Review of Some Recent Studies,
W82-04942 2H

Deep Drainage and Water Use of Forests and Pastures Grown on Deep Sands in a Mediterranean Environment,
W82-05629 4B

AUSTRIA
Control of Bulking Sludge--Practical Experiences in Austria,
W82-05423 5D

AUTOMATION
Ultrasonic Sensors for Monitoring Flows and Sludge Solids Concentrations in Water and Waste-Water Treatment,
W82-04842 5D

Application of Electro-Osmosis to Dewatering Sludges,
W82-04843 5D

Package Anaerobic Sludge Digestion.
W82-04850 5D

New Telemetry System for the Cambridge Water Company.
W82-04852 5F

A Low-Cost Multichannel Recording Piezometer System for Wetland Research,
W82-05076 7B

Lateral Move Irrigation Offers Advantages for Rectangular Fields.
W82-05080 3F

Computer Interfaced Systems for Biological Monitoring of Water Quality,
W82-05158 5A

Automated Biomonitoring Applications in Remote Water Quality Surveillance and Time Rated Toxicological Assay,
W82-05305 7B

Automation of the Seine Water Treatment Station at Morsang and of the Water Softening Station at Villeneuve-La-Garenne (Automatisation de la Station de Traitement d'Eau de Seine a Morsang et de la Station d'Adoucissement de Villeneuve-La-Garenne),
W82-05364 5F

AUTOMATION

A Computer-Based Centralized Control and Supervisory System for the Davyhulme Sewage Treatment Works,
W82-05472 5D

'Computerized' Means Cost-Effective for Sewage Treatment,
W82-05720 5D

Conversion of Rapid Gravity Filters to Fully Automatic Operation Using a Programmable Logic Controller,
W82-05802 5F

The Chertsey Automation Project at North Surrey,
W82-05805 5F

AVAILABLE WATER

Water Resources of the Walker River Indian Reservation, West-Central Nevada,
W82-05235 6B

Soil Water Availability,
W82-05623 2G

The Physical Environment of the Colorado River Basin,
W82-05891 6D

AXISYMMETRIC PIPE FLOW

Finite-Amplitude Stability of Axisymmetric Pipe Flow,
W82-05087 8B

BACKWASH

Conversion of Rapid Gravity Filters to Fully Automatic Operation Using a Programmable Logic Controller,
W82-05802 5F

BACTERIA

Disinfection Efficiencies of Chlorine Dioxide in a Gravity Flow Contractor,
W82-04782 5D

The Assessment of the Possible Inhibitory Effect of Dyestuffs on Aerobic Waste-Water Bacteria, Experience with a Screenint Test,
W82-04825 5C

Comparison of Coliphage aad Bacterial Aerosols at a Wastewater Spray Irrigation Site,
W82-04830 3C

Isolation and Characterization of Cellulolytic Bacteria from Activated Sludge,
W82-04854 5D

Bacteriological Quality of Surface and Subsurface Runoff from Manured Sandy Clay Loam Soil,
W82-04880 2A

Biosorption of Hydrophobic Organic Pollutants by Mixed Microbial Populations,
W82-04885 5B

Distribution of Methanogenic and Sulfate-Reducing Bacteria in Near-Shore Marine Sediments,
W82-04894 2L

Coprostanol and Bacterial Indicators of Faecal Pollution in the Scheldt Estuary,
W82-04923 5A

Seasonal Distribution of Bdellovibrios at the Mouth of the Patuxent River in the Chesapeake Bay,
W82-04924 2L

Preliminary Screening of Bacterial Components as Organic Precursors to the Formation of Trihalomethanes,
W82-04957 5F

Measurement of Effects of Carbaryl in Surface Water on Fecal Pollution Indicator Bacteria by Use of Plate Counts and Respirometry,
W82-05019 5A

Utilization of Organic Phosphates by Selected Bacteria and Algae,
W82-05024 5G

Dynamics of the Number of Bacteria and Conversion of Readily Oxidizable Substances in Small Rivers,
W82-05237 5A

Sulfur Bacterial Problems Revisted,
W82-05264 5B

Studies of Nitrification in a Coke-Waste Activated Sludge Process,
W82-05295 5D

Heterotrophic Assimulation of Phytoplankton as an Integral Part of the Self Purification of Natural Waters,
W82-05326 1A

An Electron Microscopic Study of the Forms of Bacteria in the Surface Film of the Water,
W82-05452 2H

Influence of High Partial Pressure of Carbon Dioxide and/or Oxygen on Nitrification,
W82-05498 5D

Nitrate Reduction by Pseudomonas SPP.: Antagonism by Fermentative Bacteria,
W82-05499 5B

Fecal Coliform Densities in a Western Watershed,
W82-05618 5B

Die-Away Kinetics of Aerosolized Bacteria from Sprinkler Application of Wastewater,
W82-05706 5D

Indicator Bacteria Survival under Laboratory Conditions,
W82-05853 5A

BACTERIAL ANALYSIS

Comparison of Various Bacterial Indicators of Fecal Contamination of the Seine in the Paris Region (Comparison de Differents Indicateurs Bacteriens de Contamination Fecale sur la Seine en Region Parisienne),
W82-04763 5A

Ammonium Uptake by Micronesian Species of Gracilaria (Rhodophyta),
W82-05311 5G

BACTERIAL PHYSIOLOGY

Utility of the Microtox Luminescent Bacterial Assay for the Rapid Assessment of Aquatic Pollution,
W82-05162 5A

BACTERIOPLANKTON

Interrelationships in the Development of the Three Structural Components of the Plankton in the Off-Bottom Zone of Lakes,
W82-05451 2H

BALTIC SEA

Investigations on the Sedimentation in the Darst-Zingst Bodden Chain - A Contribution to Establishment of an Energy and Matter Balance in the Ecosystem. Part 2: Research on the Sedimentation of Plankton. (Untersuchungen Zur Sedimentation in der Darss-Zingster Boddenkette Ein Beitrag zur Aufstellung Einer Energie-und-Stoffbilanz im Okosystem. Tiel 2: Untersuchungen zur Sedimentation des Planktons),
W82-04761 2L

Investigations on the Sedimentation in the Darss-Zingst Bodden Waters - A Contribution to the Establishment of an Energy and Matter Balance in the Ecosystem. Part 1: The Determination of the Rate of Sedimentation and Productivity Factors of Sedimented Material (Untersuchungen zur Sedimentation in den Darss-Zingster Boddengewassern - Ein Beitrag zur Aufstellung Einer Energie- und Stoffbilanz im Okosystem. Teil 1: Die Bestimmung der Sedimentationsrate und Die Erfassung Produktionsbiologisch Wichtiger Parameter des Sedimentierten Materials).
W82-04762 2L

BALTIMORE

Galvanized Steel Stalls Treatment Plant Corrosion,
W82-05167 8G

BANK EROSION

Bend Theory of River Meanders. Part 1. Linear Development,
W82-05085 2E

A Field Technique to Directly Measure River Bank Erosion,
W82-05410 7B

BASALTS

Ground-Water Management in Basalts,
W82-04931 4B

BASE FLOW

Base Flow of Streams in Nassau County Sewer Districts 2 and 3, Long Island, New York, 1978-79,
W82-04980 2E

BASELINE STUDIES

Research on Piezodialysis - Sixth Report,
W82-05294 3A

BAYS

Gas-Chromatographic Speciation of Methylstannanes in the Chesapeake Bay Using Purge Trap Sampling with a Tin-Selective Dector,
W82-04808 5A

The Tidal Stream in the German Bight,
W82-05190 2L

Influence of Water Movements and Other Factors on Distribution and Transport of Heavy Metals in a Shallow Bay (Canada),
W82-05205 5B

BDELLOVIBRIOS

Seasonal Distribution of Bdellovibrios at the Mouth of the Patuxent River in the Chesapeake Bay,
W82-04924 2L

BEAR CREEK

Life History and Habitat Utilization of Cutthroat Trout (Salmo Clarki) in a Headwater Stream on the Olympic Peninsula, Washington,
W82-05306 5C

BED LOAD

Bed Load Fluctuation: Applications,
W82-05000 2J

Hindered Bedload Settling as a Model of Sand Bed Planation by Water Waves,
W82-05607 2J

Bedload and Size Distribution in Paved Gravel-Bed Streams,
W82-05795 2J

BEDROCK

Bedrock Aquifers in the Lower Dirty Devil River Basin Area, Utah, with Special Emphasis on the Navajo Sandstone,
W82-05220 7C

Radium Content and the 226Ra/228Ra Activity Ratio in Groundwater from Bedrock,
W82-05450 2K

BEET SUGAR INDUSTRY
Fluid Flow Pattern in Upflow Reactors for Anaerobic Treatment of Beet Sugar Factory Wastewater,
W82-05372 5D

BENEFITS
A Review of the Benefit-Cost Analyses of Two Southern Alberta Dams,
W82-05766 6B

BENTHIC FAUNA
Polycyclic Aromatic Hydrocarbons in Sediments and Associated Benthos in Lake Erie,
W82-04882 5A

Some Data on the Fauna and Ecology of Metopidae (Infusoria) in Kiev Reservoir,
W82-05332 2H

Benthos Investigations: Sediment Boxes or Natural Bottom,
W82-05378 5C

Effect of the Spring Flood Regime on the Development of North Casplan Zoobenthos,
W82-05596 2E

BENTHOS
Benthos and Zooplankton of Coal Strip Mine Ponds in the Mountains of Northwestern Colorado, U.S.A.,
W82-04946 5C

BENZENES
Elimination of Hexachlorobenzene (HCB) by Rainbow Trout (Salmo Gairdneri), and an Examination of Its Kinetics in Lake Ontario Salmonids,
W82-05195 5B

BERLIN
Boron Status of Berlin Waters (Bor-Status Berliner Gewasser),
W82-04767 5A

Advanced Wastewater Treatment for Groundwater Recharge--Berlin Recharge Project (Recyclage et Traitement D'Eaux usees pour Recharger une nappe Souterraine: L'Installation Pilote de Berlin),
W82-04831 5D

BICARBONATES
Phytoplankton Responses to Ground Water Addition in Central Florida Lakes,
W82-05747 5C

BIELERSEE
Horizontal Distribution of Chlorophyll in the Bielersee (Die Horizontale Verteilung von Chlorophyll Im Bielersee),
W82-05007 2H

BIGHTS
The Tidal Stream in the German Bight,
W82-05190 2L

BIOACCUMULATION
Use of the Partition Coefficient as an Indicator of Bioaccumulation Tendency of Dyestuffs in Fish,
W82-04820 5B

Biosorption of Hydrophobic Organic Pollutants by Mixed Microbial Populations,
W82-04885 5B

The Use of Algae as Biological Accumulators for Monitoring Aquatic Pollutants,
W82-05163 5A

BIOASSAY
Algal Bioassay of the Portage Lakes, Summit County, Ohio,
W82-04813 2H

Algal Bioassay of the Water from Two Linked but Contrasting Welsh Lakes,
W82-04934 2H

Biological Monitoring of Hazardous Wastes in Aquatic Systems,
W82-05154 5A

Enzymes and Other Biochemical Indicators of Toxicant Effects in Fishes,
W82-05155 5C

Overview and Assessment of Biological Sensing,
W82-05156 5C

Utility of the Microtox Luminescent Bacterial Assay for the Rapid Assessment of Aquatic Pollution,
W82-05162 5A

Effects of Treated Municipal Wastewater on the Hepatic, Xenobiotic, and Steroid Metabolism in Trout,
W82-05406 5C

Bioassays and the Algal Populations of Hastings Lake, Alberta, Canada,
W82-05484 2H

Use of Algal Fluorescence for an Automated Biological Monitoring System,
W82-05728 5A

BIOCHEMICAL OXYGEN DEMAND
Device for Continuous Measurement of Primary Production of Water Bodies and Biochemical Oxygen Demand,
W82-05028 7B

Inhibition of Nitrogenous BOD and Treatment Plant Performance Evaluation,
W82-05323 5D

Re-Examining the Kinetics of the Biochemical Oxidation of Sewage,
W82-05409 5D

BIOCHEMISTRY
Humic Substances,
W82-05148 5B

BIODEGRADATION
Effect of Mixed Liquor Suspended Solids Concentration on the Biodegradation of Nitrilotriacetic Acid in the Activated Sludge Process,
W82-04829 5C

Microbial Degradation of 14C-Diphenylamine in a Laboratory Model Sewage Sludge System,
W82-04832 5D

Biodegradation of Hazardous Organic Pollutants,
W82-04910 5B

Utilization of Organic Phosphates by Selected Bacteria and Algae,
W82-05024 5G

Literature Study of the Biodegradability of Chemicals in Water: Volumes 1 and 2,
W82-05055 5D

Decomposition of Urea by Size-Fractionated Planktonic Community in a Eutrophic Reservoir in Japan,
W82-05095 2H

Microbial Removal of Hazardous Organic Compounds,
W82-05177 5D

Biodegradation of Synthetic Crude Oil in Two Rivers of Northern Alberta, Canada,
W82-05486 5B

BIODETECTION
Enzymes and Antibodies as Sensors of Toxic Substances,
W82-05160 5A

BIOFILMS
Kinetics of Biofilm Nitrification,
W82-05374 5D

BIOFILTERS
The Use of Container-Reared Cultures of Cladocera in Polishing Fish Farm Effluents,
W82-05327 5D

Biofiltration Design Based on Volumetric Loading,
W82-05698 5D

BIOINDICATORS
Comparison of Various Bacterial Indicators of Fecal Contamination of the Seine in the Paris Region (Comparison de Differents Indicateurs Bacteriens de Contamination Fecale sur la Seine en Region Parisienne),
W82-04763 5A

Mytilus Californianus as a Bioindicator of Trace Metal Pollution: Variability and Statistical Considerations,
W82-04776 5A

New Developments in Automated Biosensing from Remote Water Quality Stations and Satellite Data Retrieval for Resources Management,
W82-04800 7B

Pixe Trace Element Analysis of an Aquatic Plant as Indicator of Heavy Metal Pollution,
W82-04818 5A

Data Acquisition and Evaluation in Biological Monitoring Systems,
W82-04944 5A

The Use of the Three-Ridge Clam (Amblema Perplicata) to Monitor Trace Metal Contamination,
W82-04948 5A

Enzymes and Other Biochemical Indicators of Toxicant Effects in Fishes,
W82-05155 5C

New In-Situ Techniques in Biomonitoring,
W82-05157 5A

Computer Interfaced Systems for Biological Monitoring of Water Quality,
W82-05158 5A

Bioprobes for the Monitoring of Toxic Compounds and Hazardous Materials in Water,
W82-05161 5A

The Use of Algae as Biological Accumulators for Monitoring Aquatic Pollutants,
W82-05163 5A

Biological Monitoring, Part IV - Toxicity Testing,
W82-05339 5C

Biological Monitoring. Part V - Preference and Avoidance Studies,
W82-05340 5C

BIOLOGICAL FILTERS
Production and Conditioning of Sludges from a High-Rate Biological Filter,
W82-05473 5D

BIOLOGICAL OXYGEN DEMAND
Strategies for the Control of Activated Sludge Plants Treating Industrial Wastewaters,
W82-04838 5D

BIOLOGICAL OXYGEN DEMAND

Quantitative Assessment of Filamentous Algae as a Source of Deteriorating Water Quality in Canals,
W82-05593 5B

Chemometric Modeling of Wastewater Treatment Processe,
W82-05858 5D

BIOLOGICAL PROCESSES
Comprehensive Analysis of Nitrification of Chemical Processing Wastewaters,
W82-05271 5D

BIOLOGICAL PROPERTIES
Biological Monitoring, Part IIA - Receiving System Functional Methods, Relationships and Indices,
W82-05013 5A

BIOLOGICAL TREATMENT
Suppression of Break Point Prechlorination by Fast Biological Filtration, Comparative Study of Clarification Efficiencies Obtained by Single or Multilayered Blankets (Suppression de la Prechloration au Break Point par Filtration Biologique Rapide: Etude Comparee de L'efficacite de Decanteurs Biologiques a Lits Fluidises Simples ou Superposes),
W82-04765 5F

Effect of Rotation Speed on Reaction Rate on a Rotating Biological Contactor,
W82-04992 5D

Development of Water Treatment in France (Evolution dans le Traitement des Eaux en France: Quelques Exemples d'Actualite),
W82-05367 5F

BIOLOGICAL WASTEWATER TREATMENT
Pollution: Cleaning Up with the Water Hyacinth,
W82-04770 5D

Nitrification in the Sequencing Batch Biological Reactor,
W82-05254 5D

Does Conventional Sewage Treatment Meet the Demands of the 1980's,
W82-05407 5D

Some Perspectives in the Modelling of Biological Treatment of Wastewaters,
W82-05430 5D

Energy Conservation and Alternative Energy Sources in Wastewater Treatment,
W82-05440 5D

Chemical and Biochemical Oxygen Demand as Indicators of Biodegradable Substrate Concentration,
W82-05466 5D

Selected Organic Pesticides, Behavior and Removal from Domestic Wastewater by Chemical and Physical Processes,
W82-05481 5D

Comparative Performance of Rotating Biological Contractors Using Air and Pure Oxygen,
W82-05859 5D

BIOMASS
Metabolic Activity of Herbivorous Zooplankton in Lake Kinneret (Israel) During 1972-1977,
W82-05074 2H

Biomass and Annual Production of the Freshwater Mussel Elliptio Complanata in an Oligotrophic Softwater Lake,
W82-05104 2H

Bioassays and the Algal Populations of Hastings Lake, Alberta, Canada,
W82-05484 2H

Effect of the Spring Flood Regime on the Development of North Casplan Zoobenthos,
W82-05596 2E

The Mechanism of Uranium Biosorption by Rhizopus Arrhizus,
W82-05723 5D

BIOMONITORING
Overview and Assessment of Biological Sensing,
W82-05156 5C

New In-Situ Techniques in Biomonitoring,
W82-05157 5A

BIOTRANSFORMATION
Contents of Chlordane-, PCB- and DDT-Compounds and the Biotransformation Capacity of Fishes in the Lake Area of Eastern Finland,
W82-04827 5A

BLACK SEA
Manganese, Zinc and Copper in Hydrobionts in the Danube and the Northwestern Black Sea,
W82-05458 5B

BLUEBERRIES
A Survey of Azinphos Methyl and Azinphos Methyl Oxon in Water and Blueberry Samples from Hancock and Washington Counties of Maine,
W82-05376 5B

BORON
Boron Status of Berlin Waters (Bor-Status Berliner Gewasser),
W82-04767 5A

BOSTON
Drought Management: Expecting the Unexpected,
W82-05649 3D

BOTSWANA
Histopathological Changes in the Liver and Brain of Fish Exposed to Endosulfan Insecticide During Tsetse Fly Control Operations in Botswana,
W82-05630 5C

The Likelihood of Active Groundwater Recharge in the Botswana Kalahari,
W82-05657 4B

BOTTOM SEDIMENTS
Metal Ion Complex Formation Constants of Some Sedimentary Humic Acids with Zn(II), Cu(II) and Cd(II),
W82-05136 2K

Fluxes of Polycyclic Aromatic Hydrocarbons to Marine and Lacustrine Sediments in the Northeastern United States,
W82-05138 5B

Anthropogenically Derived Changes in the Sedimentary Flux of Mg, Ni, Cu, Zn, Hg, Pb, and P in Lough Neagh, Northern Ireland,
W82-05145 5B

BOTTOMLAND
The Ecology of Bottomland Hardwood Swamps of the Southeast: A Community Profile,
W82-05054 6G

BOUNDRY LAYERS
A Laboratory and Theoretical Study of the Boundary Layer Adjacent to a Vertical Melting Ice Wall in Salt Water,
W82-05084 2C

BRAZIL
Turbines for Itaipu,
W82-04955 8C

BREWING INDUSTRY
Control of Sludge Bulking in the Brewing Industry,
W82-05260 5D

BRINE DISPOSAL
An Assessment of Geothermal Development in the Imperial Valley of California; Volume 2 - Environmental Control Technology,
W82-05213 5E

BRITISH COLUMBIA
Variation in Fecal Pollution Indicators Through Tidal Cycles in the Fraser River Estuary,
W82-05384 5A

The Uncertain Quest for a Management Strategy in the Fraser Estuary,
W82-05392 6F

New Strategies for Water Resource Planning in British Columbia,
W82-05395 6E

Water Quality Management in British Columbia,
W82-05767 5C

Irrigation Efficiency in Orchards,
W82-05768 3F

The Okanagan Basin Agreements--An Example of Integrated Water Resource Planning in British Columbia,
W82-05779 6E

BROMINE
Comparative Disinfection by Bromine Chloride and Chlorine of Viruses and Bacteria in Wastewater,
W82-05446 5D

BULKING SLUDGE
Relationship Between Organic Loading, Dissolved Oxygen Concentration and Sludge Settleability in the Completely-Mixed Activated Sludge Process,
W82-05441 5D

CACHE LA POUDRE RIVER BASIN
Water Reuse Planning by Means of an Input-Output Table,
W82-04794 6A

CADILLAC
Phosphorus and Nitrogen Removal at Cadillac, Michigan,
W82-05270 5D

CADMIUM
The Use of the Three-Ridge Clam (Amblema Perplicata) to Monitor Trace Metal Contamination,
W82-04948 5A

A Simple and Rapid Method for the Determination of Lead and Cadmium in Sediment by Graphite Furnace Atomic Absorption Spectrometry,
W82-05020 5A

Determination of Cadmium in Lake Michigan by Mass Spectrometric Isotope Dilution Analysis or Atomic Absorption Spectrometry Following Electrodeposition,
W82-05040 5A

Extraction and Spectrophotometric Determination of Cadmium Based on the Formation of a Ternary Complex with Cadion and 1,10-Phenanthroline,
W82-05041 5A

Industrial Waste Pretreatment and EPA Cadmium Limitations,
W82-05443 5E

CALCIUM CARBONATE
Acid Pond Drainage,
W82-05199 5G

Effects of Increased Atmospheric C02 on Great Lakes,
W82-05209 2H

CALIBRATIONS
Simplifying Neutron Moisture Meter Calibration,
W82-05173 7B

CALIFORNIA
Barriers to Effective Ground-Water Management: The California Case,
W82-04917 4B

Placer Mining and Salmon Spawning in American River Basin, California,
W82-05200 8I

The Ecology of Southern California Coastal Salt Marshes: A Community Profile,
W82-05215 2H

California's Peripheral Canal: Skirting the Delta - and the Issues,
W82-05411 4A

Five Year Water Resources Research Plan for the State of California,
W82-05532 6B

Efficient Water Use in California: Conjunctive Management of Ground and Surface Reservoirs,
W82-05628 4B

Map of the Antelope Valley-East Kern Water Agency Area, California, Showing Ground-Water Subunits and Areas, and Dissolved-Solids Concentrations, 1970-80,
W82-05851 7C

Trap Efficiency Study, Highland Creek Flood Retarding Reservoir Near Kelseyville, California, Water Years 1966-77,
W82-05852 2J

CALIFORNIA BIGHT
Extractable Organic Matter in Municipal Wastewaters. I. Petroleum Hydrocarbons: Temporal Variations and Mass Emission Rates to the Ocean,
W82-05142 5B

CALIFORNIAGRASS
Irrigation of Californiagrass with Domestic Sewage Effluent: Water and Nitrogen Budgets and Crop Productivity,
W82-05153 3C

CALOOSAHATCHEE RIVER
Algal Conditions in the Caloosahatchee River (1975-79) Lake Okeechobee to Franklin Lock, Florida,
W82-05222 5C

CALORIMETRY
Calorific Value of Wastewater Plant Sludges,
W82-04997 5E

CAMBRIDGE WATER COMPANY
New Telemetry System for the Cambridge Water Company.
W82-04852 5F

CAMPSITES
Effects of Use Pattern, Cover, Soil Drainage Class, and Overwinter Changes on Rain Infiltration on Campsites,
W82-04858 2G

CANADA
Weak Controls from Sea to Shining Sea,
W82-05035 5B

Seismicity in the Mica Reservoir (McNaughton Lake) Area: 1973-1978,
W82-05196 8E

Influence of Water Movements and Other Factors on Distribution and Transport of Heavy Metals in a Shallow Bay (Canada),
W82-05205 5B

A Federal Perspective on River Basin Management,
W82-05388 6E

Determination of Mutagenic Potential and Organic Contaminants of Great Lakes Drinking Water,
W82-05398 5A

Organochlorine Residues in Suspended Solids Collected from the Mouths of Canadian Streams Flowing into the Great Lakes 1974-1977,
W82-05635 5B

Oxygenation of the Avon River,
W82-05730 5G

Indications of Ground Water Influences on Nutrient Transport Through Schwatka Lake, Yukon Territory,
W82-05741 5B

Northwestern Ontario River Dimensions,
W82-05742 6G

Selecting a Method for Estimating Substance Loadings,
W82-05746 5B

Leaching Fractions and Salt Status of Two Irrigated Gypsum-Rich Soils in Southern Alberta,
W82-05762 2G

Physicochemistry of Water in the St. Lawrence Gulf and Estuary (Physico-Chimie des eaux du Golfe et de l' Estuaire Saint-Laurent),
W82-05763 5B

On Hydrological Data Needs in Canada,
W82-05764 7B

A Review of the Benefit-Cost Analyses of Two Southern Alberta Dams,
W82-05766 6B

Water Quality Management in British Columbia,
W82-05767 5C

Irrigation Efficiency in Orchards,
W82-05768 3F

The Mackenzie River Basin Study,
W82-05778 4A

CANAL DESIGN
Discharge Capacity of Large Streams Under an Ice Cover,
W82-05106 2E

Hydraulic Calculations of Stable Unlined Canals by the Vertical Velocity Distribution Method,
W82-05108 8A

Calculation of Large Unlined Canals,
W82-05131 8B

Formation of a Stable Canal Channel,
W82-05584 8B

CANAL LININGS
Use of Watertight Film Facings for Repair Works on the Great Stavropol Canal,
W82-05117 8G

Salinity Control Measures for Grand Valley,
W82-05894 3F

CANALS
Resistance of Beauharnois Canal in Winter,
W82-04998 2C

California's Peripheral Canal: Skirting the Delta - and the Issues,
W82-05411 4A

Quantitative Assessment of Filamentous Algae as a Source of Deteriorating Water Quality in Canals,
W82-05593 5B

Methoxychlor Residues in Treated Irrigation Canal Water in Southcentral Idaho,
W82-05726 5B

$12.6 M Repairs Bill for Ruahihi Canal.
W82-05880 8D

CANOPY
The Impact of Managed Streamside Timber Removal on Cutthroat Trout and the Stream Ecosystem,
W82-05538 5C

CAPE TOWN
Water to the South-Western Cape Keeping Up with the Demand.
W82-04887 3C

CAPITAL COSTS
Municipal Pollution Abatement Report card: Significant Progress,
W82-05861 5D

CARBARYL
Measurement of Effects of Carbaryl in Surface Water on Fecal Pollution Indicator Bacteria by Use of Plate Counts and Respirometry,
W82-05019 5A

CARBOHYDRATES
Carbohydrates and Proteins Removals in Activated-Sludge Procedure,
W82-05090 5D

CARBON CYCLE
Plankton Metabolism and Carbon Processes in the Amazon River, Its Tributaries, and Floodplain Waters, Peru-Brazil, May-June 1977,
W82-05197 2K

CARBON DIOXIDE
Effects of Increased Atmospheric C02 on Great Lakes,
W82-05209 2H

Carbon Limitation of Biomass Production in High-Rate Oxidation Ponds,
W82-05373 5D

Influence of High Partial Pressure of Carbon Dioxide and/or Oxygen on Nitrification,
W82-05498 5D

Foreseeable Effects of CO2-Induced Climatic Change: Freshwater Concerns,
W82-05574 2B

CARBON FILTERS
Extended Dechlorination Studies with Granular Activated Carbon Filters,
W82-05257 5F

CARBON ISOTOPES
The Occurrence and Origin of Methane in Some Groundwater Flow Systems,
W82-04925 2K

CARBON TETRACHLORIDE
An Environmental Health Survey of Drinking Water Contamination by Leachate from a Pesticide Waste Dump in Hardeman County, Tennessee,
W82-05203 5B

CARCINOGENS
Biotransformation of N-Phenyl-Beta-Naphthylamine to Beta-Naphthylamine in a Laboratory Sludge System,
W82-04824 5B

Mutagens, Carcinogens and the Water Cycle,
W82-05468 5A

CARROLL COUNTY
Littletown Quadrangle: Hydrogeology,
W82-04984 7C

CARSON CITY QUADRANGLE
Flood and Debris Flood Hazards Map, Carson City Quadrangle,
W82-05217 7C

CASE STUDIES
Case Study of Prediction of Sulfide Generation and Corrosion in Sewers,
W82-05267 8G

CASPIAN SEA
Damming of the Kara-Bogaz-Gol Strait without Side Diversion of the Flow,
W82-05114 8A

CATALYSTS
Saving Energy by Catalytic Reduction of Oxygen in Feedwater,
W82-05183 5F

CATCHMENTS
A Review of Catchment Experiments to Determine the Effect of Vegetation Changes on Water Yield and Evapotranspiration,
W82-05647 4C

CAVITATION
Concrete for Surfaces of High-Head Spillways,
W82-05110 8F

Survey of Present Knowledge on Cavitation in Liquids Other Than Cold Water (Thermodynamic Effect),
W82-05280 8B

CEMENT
Consider Soil-Cement for Erosion and Seepage Control,
W82-05039 8F

CENTRAL ILLINOIS
Assessment of a Regional Aquifer in Central Illinois,
W82-05052 2F

CENTRIFUGATION
Predicting Full-Scale Batch Thickener Performance Using the Frozen-Image Centrifuge,
W82-05185 5E

CHACO REGION
Stripmining Arid Navajo Lands in the US: Threats to Health and Heritage,
W82-05036 6D

CHALK AQUIFER
Evidence for a Shallow Highly-Permeable Zone in the Chalk of Hampshire, U.K.,
W82-05645 2F

CHANNEL EROSION
Hydraulic Calculations of Stable Unlined Canals by the Vertical Velocity Distribution Method,
W82-05108 8A

CHANNEL FLOW
Downstream Reduction of Rural Channel Size with Contrasting Urban Effects in Small Coastal Streams of Southeastern Australia,
W82-04862 2E

CHANNEL IMPROVEMENT
Stream Improvement: The Chicod Creek Episode,
W82-05717 4D

Resolving the Fish vs Flood Control Controversy on the Vedder River,
W82-05765 4A

CHANNEL MORPHOLOGY
Downstream Reduction of Rural Channel Size with Contrasting Urban Effects in Small Coastal Streams of Southeastern Australia,
W82-04862 2E

CHARTS
Recording Raingage Modifications,
W82-05665 7B

CHATTAHOOCHEE NATIONAL FOREST
Impact of Hexazinone on Invertebrates After Application to Forested Watersheds,
W82-05206 5C

CHELATING AGENTS
Decomposition of Chelates Leached from Waste Disposal Sites,
W82-04879 5B

Low Pressure Membrane Separation Process to Remove Heavy Metal Complexes,
W82-05284 5D

CHELATION
Procedure for Investigating Metallic Ion Complexing in Natural Waters,
W82-05595 5A

CHEMICAL ANALYSIS
Boron Status of Berlin Waters (Bor-Status Berliner Gewasser),
W82-04767 5A

Reliability of Analytical Methods for Anaerobic Municipal Solid Waste Samples,
W82-04789 5A

Gas-Chromatographic Speciation of Methylstannanes in the Chesapeake Bay Using Purge Trap Sampling with a Tin-Selective Dector,
W82-04808 5A

Quantification of Octachlorostyrene and Related Compounds in Great Lakes Fish by Gas Chromatography-Mass Spectrometry,
W82-04993 5A

Problems of the Detection of Organic Trace Substances in Water (Zu Problemen des Nachweises Organischer Spurenstoffe im Wasser),
W82-05093 5A

CHEMICAL COAGULATION
Electrophoretic Mobility Measurements in Coagulation with Aluminum Salts,
W82-04790 5F

A Survey of Phosphorus Removal in Lower Great Lakes Municipal Treatment Plants,
W82-05256 5D

Selected Organic Pesticides, Behavior and Removal from Domestic Wastewater by Chemical and Physical Processes,
W82-05481 5D

CHEMICAL COMPOSITION
Effect of Soil Slope and Rainfall Characteristics on Phosphorus in Runoff,
W82-04859 5B

Composition of Estuarine Colloidal Material: Major and Trace Elements,
W82-05137 2L

The Role of Agricultural Sediments and Chemicals in Eutrophication,
W82-05447 2H

Fluorapatite and Fluorite Solubility Controls on Geothermal Waters in Yellowstone National Park,
W82-05449 2K

Salt and Trace Element Composition of the Water of Lake Malinovoye (Altai Territory); as a Habitat of Artemia Salina,
W82-05455 2H

CHEMICAL DEGRADATION
Literature Study of the Biodegradability of Chemicals in Water: Volumes 1 and 2,
W82-05055 5D

CHEMICAL OXYGEN DEMAND
Calorific Value of Wastewater Plant Sludges,
W82-04997 5E

Relationship Between Organic Loading, Dissolved Oxygen Concentration and Sludge Settleability in the Completely-Mixed Activated Sludge Process,
W82-05441 5D

CHEMICAL PRECIPITATION
Does Conventional Sewage Treatment Meet the Demands of the 1980's,
W82-05407 5D

Phosphorus Reduction Studies,
W82-05408 5D

The Chemistry of Suspended Matter in Esthwaite Water, A Biologically Production Lake with Seasonally Anoxic Hypolimnion,
W82-05416 2K

Experience from 10 Years Advanced Wastewater Treatment--Technology and Results,
W82-05424 5D

CHEMICAL PROPERTIES
On the Chemistry of Some Salt Lakes and Ponds in Yugoslavia,
W82-04929 2H

On the Chemistry and Biota of Some Saline Lakes in Western Australia,
W82-04940 2H

Chemistry, Physics and Evolution of Antarctic Saline Lakes,
W82-05100 2H

Chemical Character of Water in the Red River Alluvial Aquifer, Louisiana,
W82-05228 7C

CHEMICAL REACTION
Humic Substances,
W82-05148 5B

CHEMICAL REACTIONS
Comparison of Photochemical Behavior of Various Humic Substances in Water: I. Sunlight Induced Reactions of Aquatic Pollutants Photosensitized,
W82-04914 2K

Comparison of Photochemical Behavior of Various Humic Substances in Water: II. Photosensitized Oxygenations,
W82-04915 2K

Numerical Simulation of the Transport and Speciation of Nonconservative Chemical Reactants in Rivers,

DENSITY
Several Plume Flows in Pure and Saline Water at Its Density Extremum,
W82-05088 2E

DENSITY CURRENTS
A Note on the Structure of the Head of an Intrusive Gravity Current,
W82-05089 2E

DEPOSITION
Downcore Variation in Sediment Organic Nitrogen,
W82-05124 2H

DEPOSITION (SEDIMENTS)
Determination of Recent Desposition Rates in Lake Constance with Radioisotopic Methods,
W82-05625 5B

DERBY
Try Chemical Tests If Industrial Wastes Are Strong,
W82-05037 5D

DESALINATION
Reconnaissance Samplings and Characterization of Aquatic Humic Substances at the Yuma Desalting Test Facility, Arizona,
W82-04983 3A

Low Temperature Evaporation Plants,
W82-05118 3A

Parametric Analysis of Direct-Contact (Pistonless) Work Exchanger for Reverse Osmosis Applications,
W82-05309 3A

Fabrication and Characterization of Metal Membranes Having Pore Charge Control for Desalination,
W82-05314 3A

Operating Experiences on a Reverse Osmosis Plant Which Converts Sea Water into Boiler Feed Water,
W82-05509 3A

Water and Salt Transport in Membranes,
W82-05537 3A

The Role of Desalting Tchnology in Water Supply, Wastewater Reuse and Industrial Applications,
W82-05543 3A

Seawater Ro Heads Japan's Water Reuse Research.
W82-05756 3A

Optimal Salinity Control Program for the Upper Colorado River Basin,
W82-05893 5G

Salinity Control Measures for Grand Valley,
W82-05894 3F

DESALINATION APPARATUS
Research on Piezodialysis - Sixth Report,
W82-05294 3A

Fabrication and Characterization of Metal Membranes Having Pore Charge Control for Desalination,
W82-05314 3A

DESALINATION PLANTS
VTE/VC for Sea Water,
W82-04909 3A

The Wellton-Mohwak Dilemma,
W82-05883 3F

DESALINTION
Foam Fractionation-Flotation as Partial Pretreatment for Reverse Osmosis,
W82-05290 3A

DESERTS
Nitrogen and Phosphorus Dynamics in Hot Desert Streams of Southwestern U.S.A.,
W82-04930 2K

DESIGN CONSIDERATIONS
How the Tyne Was Saved. Duke of Edinburgh Opens 120 Million Pound Sterling Scheme.
W82-05249 5D

DESIGN CRITERIA
Reliability and Stability of Trickling Filter Processes,
W82-04784 5D

New Flocculation Units with High Efficiency,
W82-04840 5D

An Exercise in Sludge Consolidation,
W82-04848 5D

Resonance in Hydropower Stations,
W82-04953 8C

Turbines for Itaipu,
W82-04955 8C

Restructuration of the Water Tariff System for Irrigation Districts in Mexico.
W82-04962 6C

Estimates of Resilience Indices by Simulation,
W82-05046 6A

Determination of the Optimal Height of the Bucket Lip of a Ski-Jump Spillway,
W82-05107 8B

Hydraulic Calculations of Stable Unlined Canals by the Vertical Velocity Distribution Method,
W82-05108 8A

Galvanized Steel Stalls Treatment Plant Corrosion,
W82-05167 8G

Bactericidal Agents in Wastewater Lagoons and Lagoon Design,
W82-05333 5D

Some Perspectives in the Modelling of Biological Treatment of Wastewaters,
W82-05430 5D

Pressure Distribution Design for Septic Tank Systems,
W82-05439 5E

Start-Up Problems of Sludge Dewatering Facility,
W82-05444 5D

Comparison of Isostatic and Hyperstatic Penstocks at Santa Isabel, Bolivia,
W82-05561 8A

Where to Put a Steady Discharge in a River,
W82-05632 5G

Using Pump Curves and Valving Techniques for Efficient Pumping,
W82-05666 8C

Septage and Wastewater Treatment in the Activated Sludge Process,
W82-05699 5D

Deep Shaft,
W82-05793 5D

DESIGN STANDARDS
Maximum Pressure During Water Hammer Accompanied by Discontinuity of the Flow,
W82-04772 8B

DESIGN STORMS
An Evaluation of the Urban Design Storm Concept,
W82-04960 6A

DETENTION RESERVOIRS
Settleability of Urban Runoff Pollution,
W82-05320 5G

Trap Efficiency Study, Highland Creek Flood Retarding Reservoir Near Kelseyville, California, Water Years 1966-77,
W82-05852 2J

DETERGENTS
A Preliminary Assessment of Michigan's Phosphorus Detergent Ban,
W82-04786 5G

DETRITUS
Flood and Debris Flood Hazards Map, Carson City Quadrangle,
W82-05217 7C

DEUTERIUM
The Relationship Between 018 and Deuterium in Water in Sand Columns Undergoing Evaporation,
W82-05759 2G

DEVELOPING COUNTRIES
Water-Pollution Research and Its Application in Developing Countries,
W82-05246 5G

Can the Goals of the UN Decade on Water Supply and Sanitation Be Achieved,
W82-05365 6B

Water and Wastewater Treatment in Latin America--Applied Technology,
W82-05425 5F

Environmental Aspects of Multi-Purpose Reservoir Projects in Developing Countries,
W82-05426 6G

Egypt Tackles Rural Supply Task,
W82-05754 5F

Turks Press Forward With Ambitious Dam Programme,
W82-05758 6B

DEWATERING
Improved Thermal Sludge Conditioning by Treatment with Acids and Bases,
W82-04785 5E

Application of Electro-Osmosis to Dewatering Sludges,
W82-04843 5D

A Dynamic Model Identification of the Sludge Dewatering Process,
W82-04844 5D

Calculation of Complete Interception of Groundwater Flow to 'Fully Penetrating' Excavations,
W82-04902 8C

The Booming Business in Wick Drains,
W82-05192 8G

Drainability of Aerobically Digested Biological Sludge from Textile Waste,
W82-05261 5E

Start-Up Problems of Sludge Dewatering Facility,
W82-05444 5D

Mechanisms and Methods for Polymer Conditioning of Activated Sludge,
W82-05445 5D

Use and Design Features of the Pump Unit of the UVV-3-6KM Vacuum Groundwater Lowering Installation,
W82-05587 8C

Examination of Process Parameters Affecting Sludge Dewatering with a Diaphragm Filter Press,
W82-05695 5D

DIATOMS
Algal Bioassay of the Water from Two Linked but Contrasting Welsh Lakes,
W82-04934 2H

The Effects of Dissolved Heavy Metals on Attached Diatoms in the Uintah Basin of Utah, U.S.A.,
W82-04951 5A

The pH History of Lakes in Southwestern Sweden as Calculated from the Subsoil Diatom Flora of the Sediments,
W82-05034 2H

Preliminary Investigation of the Algal Flora in the Sediments of Lake Erie,
W82-05633 5C

DIEL VARIATINS
Diel Variations of Certain Physico-Chemical Parameters of Water in Selected Aquatic Systems,
W82-05097 2H

DIFFUSIVITY
An Approximate Method of Estimating Soil Water Diffusivity for Different Soil Bulk Densities,
W82-05073 2G

DIGESTION
Use of Bench-Scale Digesters to Evaluate Full-Scale Digester Performance,
W82-05272 5D

DIGITAL COMPUTERS
Advanced Supervisory Control System for Sludge Treatment,
W82-04841 5D

Management System for Control of Process Losses and Spills in the Kraft Pulping Industry,
W82-04846 5D

DIOXINS
Determination of 2,3,7,8-Tetrachlorodibenzo-P-Dioxin in Fresh Water Fish,
W82-04883 5A

DIRTY DEVIL RIVER BASIN
Bedrock Aquifers in the Lower Dirty Devil River Basin Area, Utah, with Special Emphasis on the Navajo Sandstone,
W82-05220 7C

DISCHARGE
A New Method of Cubature Using Spline Functions,
W82-05189 2L

DISCHARGE CAPACITY
Discharge Capacity of Large Streams Under an Ice Cover,
W82-05106 2E

DISCHARGE FREQUENCY
Streamflow Characteristics of the Upper Columbia River Basin, Montana, Through 1979,
W82-05225 2E

DISCHARGE HYDROGRAPHS
Time and Frequency Domain Analyses of Hydrological Systems,
W82-05655 2E

DISCHARGE MEASUREMENT
Discharge Data at Water-Quality Monitoring Stations in Arkansas, 1980 Water Year,
W82-05841 7C

DISCHARGE MEASUREMENTS
A New Method of Cubature Using Spline Functions,
W82-04939 2L

DISCOUNT RATES
Optimal Water Pricing and Storage: The Effect of Discounting,
W82-05049 6C

DISINFECTION
Disinfection Efficiencies of Chlorine Dioxide in a Gravity Flow Contractor,
W82-04782 5D

Factors Influencing Formation of Trihalomethanes in Drinking Water with Special Reference to Swedish Conditions,
W82-04826 5F

The Hygienic Control of Swimming Baths.
W82-04853 5F

Prospects of Using Radiation Water Treatment Methods,
W82-05026 5D

Study of Chlorine Dioxide and Its Metabolites in Man,
W82-05057 5F

Development of Water Treatment in France (Evolution dans le Traitement des Eaux en France: Quelques Exemples d'Actualite),
W82-05367 5F

Chemicals in Water Treatment--Effects on Water Quality,
W82-05369 5F

Comparative Disinfection by Bromine Chloride and Chlorine of Viruses and Bacteria in Wastewater,
W82-05446 5D

DISPERSANTS
Oil Slick Mechanics,
W82-05064 5G

Dispersant Application System for the U.S. Coast Guard 32-Foot WPB,
W82-05069 5G

DISPERSION COEFFICIENT
Hydrodynamic Dispersion During Absorption in a Fine Sand 1. The Constant Concentration Case,
W82-05347 5B

DISPOSAL WELLS
Optimal Dynamic Management of Groundwater Pollutant Sources,
W82-05345 5G

DISSOLVED OXYGEN
Hypolimnion Oxygenation Studies in Clark Hill Lake,
W82-05001 5G

Continuous Measurements of Dissolved Oxygen in Water Culture by a Self-Calibrating Monitor,
W82-05015 7B

Device for Continuous Measurement of Primary Production of Water Bodies and Biochemical Oxygen Demand,
W82-05028 7B

Saving Energy by Catalytic Reduction of Oxygen in Feedwater,
W82-05183 5F

Modelling and Control of Dissolved Oxygen in an Estuary,
W82-05188 6A

A Reliable Dissolved Oxygen Probe for Waste Water Treatment Plants,
W82-05248 7B

Do Model for Discharges from Deep Impoundments,
W82-05316 2H

Re-Examining the Kinetics of the Biochemical Oxidation of Sewage,
W82-05409 5D

Relationship Between Organic Loading, Dissolved Oxygen Concentration and Sludge Settleability in the Completely-Mixed Activated Sludge Process,
W82-05441 5D

Filtering of Dissolved Oxygen Data in Stream Water Quality Analysis,
W82-05488 5B

DISSOLVED SOLIDS
Map of the Antelope Valley-East Kern Water Agency Area, California, Showing Ground-Water Subunits and Areas, and Dissolved-Solids Concentrations, 1970-80,
W82-05851 7C

Influence of Dissolved Organic Materials on Turbid Water Optical Properties and Remote-Sensing Reflectance,
W82-05869 2K

DISTILLATION
Treatment of Cooling Tower Blowdown,
W82-04908 5D

VTE/VC for Sea Water,
W82-04909 3A

Low Temperature Evaporation Plants,
W82-05118 3A

DIVERSION
A Mobile Stream Diversion System for Hazardous Materials Spills Isolation,
W82-05070 5G

DIVERSION STRUCTURES
The Long Lake Diversion: An Environmental Evaluation,
W82-05568 6G

Selection of Temporary Diversion Tunnels and Tunnel Schemes for Discharge of Water,
W82-05588 8A

Northwestern Ontario River Dimensions,

ENTRAINMENT
Entrainment Mortality of Ichthyoplankon: Detectability and Precision of Estimates,
W82-05181 5C

Aeration at High Velocity Flows,
W82-05602 8A

ENVIROMENTAL EFFECTS
Enzyme Activity and Kinetics in Substrate-Amended River Sediments,
W82-05336 5C

Flood Control and Flow Regulation Problems on the Assiniboine River,
W82-05389 4A

ENVIRONMENT
The Response of Specific Conductance to Environmental Conditions in the Everglades National Park, Florida,
W82-05464 5A

ENVIRONMENTAL CONTROL
An Assessment of Geothermal Development in the Imperial Valley of California; Volume 2 - Environmental Control Technology,
W82-05213 5E

ENVIRONMENTAL EFFECTS
A New Look at Small Power Plants. 2. The Environmental Effects,
W82-04769 6D

Acid Precipitation. 1. Causes and Consequences,
W82-04771 5C

The Influence of Water Salinity on Paludal Erosion Processes,
W82-04995 2J

Biological Monitoring, Part IIA - Receiving System Functional Methods, Relationships and Indices,
W82-05013 5A

Man-Made Storage of Water Resources--A Liability to the Ocean Environment. Part II,
W82-05126 4A

Effects of Acid Precipitation,
W82-05149 5C

Metabolic Response of Fish to Stress,
W82-05159 5C

Sulphur in the Environment: A Review,
W82-05179 5B

An Assessment of Geothermal Development in the Imperial Valley of California; Volume 1 - Environment, Health and Socio-economics,
W82-05214 6G

Sawmill Brook: An Example of Rapid Geomorphic Change Related to Urbanization,
W82-05276 4C

Impact of Discharges as a Basis for Control Measures,
W82-05354 5B

Environmental Impact of the Microbial Aerosol Emissions from Wastewater Treatment Plants,
W82-05428 5B

The Long Lake Diversion: An Environmental Evaluation,
W82-05568 6G

Modifications to Steam Channels in the Brisbane Metropolitan Area, Australia,
W82-05572 4A

The XIII Olympic Games and Environmental Quality Perspective,
W82-05703 5D

Northwestern Ontario River Dimensions,
W82-05742 6G

Impact of Energy Development upon Water and Salinity in the Upper Colorado River Basin,
W82-05886 3C

The Colorado River Salinity Problem,
W82-05889 5G

ENVIRONMENTAL IMPACT STATEMENT

Environmental Aspects of Multi-Purpose Reservoir Projects in Developing Countries,
W82-05426 6G

ENVIRONMENTAL PROTECTION

Law for Environmentalists,
W82-05813 5G

ENZYMES

Effect of Long Term Exposure to Petroleum on Mixed Function Oxygenases in Fish: Further Support for Use of the Enzyme System in Biological Monitoring,
W82-04884 5C

Enzymes and Other Biochemical Indicators of Toxicant Effects in Fishes,
W82-05155 5C

Enzymes and Antibodies as Sensors of Toxic Substances,
W82-05160 5A

Bioprobes for the Monitoring of Toxic Compounds and Hazardous Materials in Water,
W82-05161 5A

Enzyme Activity and Kinetics in Substrate-Amended River Sediments,
W82-05336 5C

EQUILIBRIUM

Theoretical Analysis of Ionic Equilibria in Natural Water,
W82-05239 2K

Ion Hydration and Ion Interaction,
W82-05310 2K

EROSION

Erosion by Submerged Circular Jets,
W82-05002 2J

Erosion by Plane Turbulent Jets,
W82-05277 8B

A Field Technique to Directly Measure River Bank Erosion,
W82-05410 7B

Erosion from Mountain Snowpack Melt,
W82-05664 2J

EROSION CONTROL

Consider Soil-Cement for Erosion and Seepage Control,
W82-05039 8F

Erosion Control Potential with Conservation Tillage in the Lake Erie Basin: Estimates Using the Universal Soil Loss Equation and the Land Resource Information System (LRIS),
W82-05661 4D

Erosivity Values for Individual Design Storms,
W82-05694 4D

EROSION RATES

A Stochastic Model of Soil Erosion,
W82-05298 2J

Potential Sediment Production Within Vegetative Communities in Oregon's Blue Mountains,
W82-05867 2J

ERROR ANALYSIS

Erosivity Values for Individual Design Storms,
W82-05694 4D

A Sensitivity and Error Analysis Framework for Lake Eutrophication Modeling,
W82-05739 5C

ESCHERICHIA COLI

Measurement of Effects of Carbaryl in Surface Water on Fecal Pollution Indicator Bacteria by Use of Plate Counts and Respirometry,
W82-05019 5A

ESTHWAITE WATER

The Chemistry of Suspended Matter in Esthwaite Water, A Biologically Production Lake with Seasonally Anoxic Hypolimnion,
W82-05416 2K

ESTIMATING EQUATION

An Approximate Method of Estimating Soil Water Diffusivity for Different Soil Bulk Densities,
W82-05073 2G

ESTIMATING EQUATIONS

Flood Peak Regionalization Using Mixed-Mode Estimation of the Parameters of the Log-Normal Distribution,
W82-05495 2E

ESTONIA

Dynamics of the Number of Bacteria and Conversion of Readily Oxidizable Substances in Small Rivers,
W82-05237 5A

ESTUARIES

Sediment Water Exchanges of Nutrients and Oxygen on Tidal Flats in the Ems-Dollart Estuary,
W82-04751 2L

Composition and Distribution of Dissolved Fluorescent Substances in the Ems-Dollart Estuary,
W82-04752 2L

Sediment Transport and Shoaling in Estuarine and Other Shallow-Water Areas,
W82-04753 2L

Determination of Trace Metals in Estuarine Sediments by Graphite-Furnace Atomic Absorption Spectrometry,
W82-04893 5A

The Ecology of Plankton Fauna in Saline River Pools,
W82-04941 2L

Composition of Estuarine Colloidal Material: Major and Trace Elements,
W82-05137 2L

Experimental Studies to Determine the Fate of Petroleum Hydrocarbons from Refinery Effluent on an Estuarine System,
W82-05144 5B

The Tidal Stream in the German Bight,
W82-05190 2L

Initial Colonization of Artificial Substrate: Community Development and Structure Studied by Scanning Electron Microscopy,
W82-05193 2L

Seasonal Temperature and Power Plant Chlorination Effects on Estuarine Invertebrates,
W82-05204 5C

Dynamic Estuary Model Performance,
W82-05319 2L

The Uncertain Quest for a Management Strategy in the Fraser Estuary,
W82-05392 6F

Contaminant Dispersion in Oscillatory Flows,
W82-05631 5B

Metal Surveys in South African Estuaries. II. Knysna River,
W82-05897 5B

Metal Surveys in South African Estuaries. I. Swartkops River,
W82-05898 2B

ESTUARINE ENVIRONMENT

Modeling: How and When to Use,
W82-04754 2L

Investigations on the Sedimentation in the Darst-Zingst Bodden Chain - A Contribution to Establishment of an Energy and Matter Balance in the Ecosystem. Part 2: Research on the Sedimentation of Plankton. (Untersuchungen Zur Sedimentation in der Darss-Zingster Boddenkette Ein Beitrag zur Aufstellung Einer Energie-und-Stoffbilanz im Okosystem. Tiel 2: Untersuchungen zur Sedimentation des Planktons),
W82-04761 2L

Investigations on the Sedimentation in the Darss-Zingst Bodden Waters - A Contribution to the Establishment of an Energy and Matter Balance in the Ecosystem. Part 1: The Determination of the Rate of Sedimentation and Productivity Factors of Sedimented Material (Untersuchungen zur Sedimentation in den Darss-Zingster Boddengewassern - Ein Beitrag zur Aufstellung Einer Energie- und Stoffbilanz im Okosystem. Teil 1: Die Bestimmung der Sedimentationsrate und Die Erfassung Produktionsbiologisch Wichtiger Parameter des Sedimentierten Materials).
W82-04762 2L

Petroleum Refinery Wastewater Induction of the Hepatic Mixed-Function Oxidase System in Pacific Staghorn Sculpin,
W82-04895 5C

Modelling and Control of Dissolved Oxygen in an Estuary,
W82-05188 6A

Benthos Investigations: Sediment Boxes or Natural Bottom,
W82-05378 5C

Sediment Mixing and Accumulation Rate Effects on Radionuclide Depth Profiles in Hudson Estuary Sediments,
W82-05868 2J

EUTROPHIC LAKES
The Rehabilitation of Norway's Largest Lake,
W82-05243 5G

Bioassays and the Algal Populations of Hastings Lake, Alberta, Canada,
W82-05484 2H

EUTROPHICATION
The Effects of Varying Culture Nitrogen and Phosphorus Levels of Nutrient Uptake and Storage by the Waterhyacinth Eichhornia Crassipes (Mart) Solms,
W82-05098 5G

Mineral Composition of Phragmites Australis in Scottish Lochs as Related to Eutrophication. I. Seasonal Changes in Organs,
W82-05099 2H

Epilimnetic and Hypolimnetic Symptoms of Eutrophication in Great Mazurian Lakes, Poland,
W82-05103 2H

Possibilities of Optimizing Processes Forming the Quality of Natural Water,
W82-05115 5G

Cyanobacterial Blooms: Carbon and Nitrogen Limitation have Opposite Effects on the Buoyance of Oscillatori,
W82-05175 5C

Nitrogen Control for the Partly Sewered Basin of Yodo River-Lake Biwa System,
W82-05244 5D

Microbial Ecology of Pectin Decomposition in Anoxic Lake Sediments,
W82-05275 2H

Treatment of Water from Eutrophied Impoundments,
W82-05368 5F

Phosphorus Reduction Studies,
W82-05408 5D

The Role of Agricultural Sediments and Chemicals in Eutrophication,
W82-05447 2H

A Sensitivity and Error Analysis Framework for Lake Eutrophication Modeling,
W82-05739 5C

EVALUATION
Computer-Aided Evaluation of Peru's Hydropower,
W82-04954 6B

Field Testing and Optimizing Efficiency of Hydro Turbines,
W82-05010 8C

Performance of a Large Advanced Waste Treatment Plant,
W82-05251 5D

Sampling Frequency Optimization Using a Water Quality Index,
W82-05268 5A

Use of Bench-Scale Digesters to Evaluate Full-Scale Digester Performance,
W82-05272 5D

Can the Goals of the UN Decade on Water Supply and Sanitation Be Achieved,
W82-05365 6B

EVAPORATION
Shale Oil Wastewater Treatment by Evaporation,
W82-04905 5D

VTE/VC for Sea Water,
W82-04909 3A

Surface Heat Fluxes from Lake Ontario: Further Verification of Lake Thermal Model,
W82-05048 2H

Atmospheric Moisture Transport and the Water Balance of the Mediterranean Sea,
W82-05050 2A

Low Temperature Evaporation Plants,
W82-05118 3A

Stability Effects on Great Lakes Evaporation,
W82-05634 2D

The Relationship Between 018 and Deuterium in Water in Sand Columns Undergoing Evaporation,
W82-05759 2G

EVAPORATION PANS
Estimation of Isotopic Exchange Parameters, Using Constant-Feed Pans,
W82-05648 2D

EVAPORATION RATE
A Floodplain Storage Model Used to Determine Evaporation Losses in the Upper Yobe River, Northern Nigeria,
W82-04863 2D

Evaporation at a High Arctic Site,
W82-04899 2D

EVAPOTRANSPIRATION
Evaluation of the Effect of Linearization of the Magnus Equation on the Accuracy of Calculating Evaporation from the Surface of Moist Soil and Transpiration,
W82-05031 2D

Influence of Seasonal Evaporative Demand on Evapotranspiration and Yield of Irrigated Wheat,
W82-05121 2D

Soil Water Availability,
W82-05623 2G

A Review of Catchment Experiments to Determine the Effect of Vegetation Changes on Water Yield and Evapotranspiration,
W82-05647 4C

New Evapotranspiration Crop Coefficients,
W82-05692 3F

A Prediction Equation for Day Night Wind Ratio Correction on Reference Crop Evapotranspiration,
W82-05722 2D

EVAPOTRANSPIRATION POTENTIAL
Improved Water and Nutrient Management Through High-Frequency Irrigation, Vol 2: Response of Peanuts to Irrigation Management at Different Crop Growth Stages,
W82-05293 3F

Improved Water and Nutrient Management Through High-Frequency Irrigation, Vol. 3: Determining the Transpiration Rate of Peach Trees Under Two Trickle Irrigation Regimes,
W82-05312 3F

EXCAVATION
Calculation of Complete Interception of Groundwater Flow to 'Fully Penetrating' Excavations,
W82-04902 8C

Frogmen's Subterranean Swim Sites Source,
W82-05501 8A

Experience in Preparing the Rock Foundation of the Dnestr Hydroelectric Station,
W82-05585 8H

Driving Large Hydraulic Tunnels by the Stepped Face Method,
W82-05586 8H

EXCESS RAINFALL
The Likelihood of Active Groundwater Recharge in the Botswana Kalahari,
W82-05657 4B

EXPLORATION
Frogmen's Subterranean Swim Sites Source,
W82-05501 8A

EXPLOSIVES
Effluent Analysis of Wastewater Generated in the Manufacture of 2,4,6-Trinitrotoluene, 2. Determination of a Representative Discharge of Ether-Extractable Components,
W82-05412 5A

Effluent Analysis of Wastewater Generated in the Manufacture of 2,4,6-Trinitrotoluene. 1. Characterization Study,
W82-05413 5A

Experience in Preparing the Rock Foundation of the Dnestr Hydroelectric Station,
W82-05585 8H

EXTENDED AERATION
Treatment of Cyanide Waste by the Extended Aeration Process,
W82-04787 5D

FALLOUT
The Impact of Acidic Precipitation and Heavy Metals on Soils in Relation to Forest Ecosystems,
W82-05534 5C

FALLOWING
Flexcrop: A Dryland Cropping Systems Model,
W82-05208 3F

FARM WASTES
Package Anaerobic Sludge Digestion.
W82-04850 5D

Bacteriological Quality of Surface and Subsurface Runoff from Manured Sandy Clay Loam Soil,
W82-04880 2A

FATE OF POLLUTANTS
Chemical Fractionation of Heavy Metals in Wastewater-Affected Soils,
W82-04781 5B

Volatilization Rates of Intermediate and Low Volatility Chemicals from Water,
W82-04817 5B

Pixe Trace Element Analysis of an Aquatic Plant as Indicator of Heavy Metal Pollution,
W82-04818 5A

Photolysis of Polycyclic Aromatic Hydrocarbons in Water,
W82-04835 5B

Biosorption of Hydrophobic Organic Pollutants by Mixed Microbial Populations,
W82-04885 5B

Biodegradation of Hazardous Organic Pollutants,
W82-04910 5B

Numerical Simulation of the Transport and Speciation of Nonconservative Chemical Reactants in Rivers,
W82-05079 5B

Experimental Studies to Determine the Fate of Petroleum Hydrocarbons from Refinery Effluent on an Estuarine System,
W82-05144 5B

Humic Substances,
W82-05148 5B

Microcomputer Water Quality Simulation Model,
W82-05191 7B

The Dissipation of Nonylphenol in Stream and Pond Water Under Simulated Field Conditions,
W82-05273 5B

Surface Chemical Theory as an Aid to Predict the Distribution and the Fate of Trace Constituents and Pollutants in the Aquatic Environment,
W82-05353 5B

A Survey of Azinphos Methyl and Azinphos Methyl Oxon in Water and Blueberry Samples from Hancock and Washington Counties of Maine,
W82-05376 5B

Overestimation of Orthophosphorus Concentrations in Surface Waters of Southern Lake Michigan: Effects of Acid and Ammonium Molybdate,
W82-05382 5A

Effect of Turbulent Dispersion on the Rate of Ammonia Nitrogen in Rivers,
W82-05418 5B

Radionuclides in Mono Lake, California,
W82-05461 5B

The Fate of Organic Pollutants in Frozen Waters: Sunlight Photodecomposition of Uracil Herbicides in Frozen Aqueous Solutions,
W82-05479 5B

Investigations into the Protective Effect of Estuarine Sediment on Virus Survival,
W82-05485 5C

Biodegradation of Synthetic Crude Oil in Two Rivers of Northern Alberta, Canada,
W82-05486 5B

Elevated Concentrations of Actinides in Mono Lake,
W82-05520 5B

FATE OF POLLUTENTS
Random Differential Equations in River Water Quality Modeling,
W82-05343 6A

FEASIBILITY STUDIES
Feasibility of Commercialized Water Treatment Techniques for Concentrated Waste Spills,
W82-05068 5G

FEDERAL JURISDICTION
A Federal Perspective on River Basin Management,
W82-05388 6E

The Recommendations of the United Nations Water Conference (Mar Del Plata, 1977) and Related Meetings, on National Water Laws,
W82-05492 6E

FEEDLOT RUNOFF
Water Quality in a Stream Receiving Dairy Feedlot Effluent,
W82-04860 5B

An Evaluation System to Rate Feedlot Pollution Potential,
W82-05207 5B

FEEDS
High-Rate Algae Ponds for Wastewater Treatment and Protein Production,
W82-05355 5D

FEEDWATER TREATMENT
Saving Energy by Catalytic Reduction of Oxygen in Feedwater,
W82-05183 5F

Field Test Evaluation Research and Development and Operation and Maintenance of Reverse Osmosis Systems and Electrodialysis Pilot Plants at Roswell Test Facility.
W82-05555 3A

FERMENTATION
Control of Sludge Bulking in the Brewing Industry,
W82-05260 5D

FERTILIZERS
Movement of Diffuse Source Pollutants in Small Agricultural Watersheds of the Great Lakes Basin,
W82-04856 5B

Application of an Approximate Analytic Method of Computing Solute Profiles with Dispersion in Soils,
W82-04876 5B

Effect of Plant Population and Nitrogen on Water-Use Efficiency of Pearlmillet in the Arid Zone of Western Rajastan,
W82-05122 2I

Irrigation Efficiency in Orchards,
W82-05768 3F

FIELD TESTS
Classification and Management of Wetlands in the Western Kentucky Coal Field,
W82-05549 5C

Field Test Evaluation Research and Development and Operation and Maintenance of Reverse Osmosis Systems and Electrodialysis Pilot Plants at Roswell Test Facility.
W82-05555 3A

FILTER MEDIA
Pharmaceutical Waste Treatment by Anaerobic Filter,
W82-05686 5D

Role of Surface Active Media in Anaerobic Filters,
W82-05816 5D

FILTER PERFORMANCE
Filtration Performance in Water and Wastewater Treatment: Theory and Measurement,
W82-05285 5D

FILTRATION
Suppression of Break Point Prechlorination by Fast Biological Filtration, Comparative Study of Clarification Efficiencies Obtained by Single or Multilayered Blankets (Suppression de la Prechloration au Break Point par Filtration Biologique Rapide: Etude Comparee de L'efficacite de Decanteurs Biologiques a Lits Fluidises Simples ou Superposes),
W82-04765 5F

Design, Construction and Operation of a New Filter Approach for Treatment of Surface Waters in Southeast Asia,
W82-04869 5F

Treatment of Secondary Sewage Effluent with a Peat-Sand Filter Bed,
W82-04871 5D

On the Use of Filters for Distinguishing Between Dissolved and Particulate Fractions in Natural Waters,
W82-05012 5A

Selective Passage of Hydrophilic Nitrogenous Organic Materials Through Macroreticular Resins,
W82-05150 5D

Ultra-High-Rate Filtration of Raw and Combined Sewer Overflows,
W82-05266 5D

Filtration Performance in Water and Wastewater Treatment: Theory and Measurement,
W82-05285 5D

Treatment of Water from Eutrophied Impoundments,
W82-05368 5F

Overestimation of Orthophosphorus Concentrations in Surface Waters of Southern Lake Michigan: Effects of Acid and Ammonium Molybdate,
W82-05382 5A

Examination of Process Parameters Affecting Sludge Dewatering with a Diaphragm Filter Press,
W82-05695 5D

Filterability of Activated Sludge in Response to Growth Conditions,
W82-05860 5D

FINANCIAL FEASIBILITY
Internal Rates of Return Derived from the Pay-Back Period,
W82-05542 6B

FINANCING
Turks Press Forward With Ambitious Dam Programme,
W82-05758 6B

FINITE DIFFERENCE METHODS
A Finite-Difference Method to Evaluate Water Hammer Phenomena,
W82-04799 8B

FINITE ELEMENT METHOD
An Enriched Finite Element for Simulation of Groundwater Flow to a Well or Drain,
W82-05652 2F

FINLAND
Recent Trends of Biocides in Pikes of the Lake Paijanne,
W82-04819 5A

Contents of Chlordane-, PCB- and DDT-Compounds and the Biotransformation Capacity of Fishes in the Lake Area of Eastern Finland,
W82-04827 5A

Radium Content and the 226Ra/228Ra Activity Ratio in Groundwater from Bedrock,
W82-05450 2K

FISH
Recent Trends of Biocides in Pikes of the Lake Paijanne,
W82-04819 5A

Use of the Partition Coefficient as an Indicator of Bioaccumulation Tendency of Dyestuffs in Fish,
W82-04820 5B

Unusual Polyhalogenated Chemical Residues Identified in Fish Tissue from the Environment,
W82-04822 5A

Contents of Chlordane-, PCB- and DDT-Compounds and the Biotransformation Capacity of Fishes in the Lake Area of Eastern Finland,
W82-04827 5A

A One Year Study of the Seasonal Variations of sDDT and PCB Levels in Fish from Heated and Unheated Areas Near a Nuclear Power Plant.
W82-04836 5C

Determination of 2,3,7,8-Tetrachlorodibenzo-P-Dioxin in Fresh Water Fish,
W82-04883 5A

Effect of Long Term Exposure to Petroleum on Mixed Function Oxygenases in Fish: Further Support for Use of the Enzyme System in Biological Monitoring,
W82-04884 5C

Data Acquisition and Evaluation in Biological Monitoring Systems,
W82-04944 5A

Quantification of Octachlorostyrene and Related Compounds in Great Lakes Fish by Gas Chromatography-Mass Spectrometry,
W82-04993 5A

Enzymes and Other Biochemical Indicators of Toxicant Effects in Fishes,
W82-05155 5C

Metabolic Response of Fish to Stress,
W82-05159 5C

Entrainment Mortality of Ichthyoplankon: Detectability and Precision of Estimates,
W82-05181 5C

The Utilization of Grass Carp, Ctenopharyngodon Idella Val., for Hydrilla Control in Lake Baldwin, Florida,

FISH FOOD ORGANISMS

Hypania Invalida in the Volga Resevoirs and Hydrobiological Monitoring,
W82-05331 2H

FISH GUIDING

Engineering Aspects of Fish Protection at Water Intakes,
W82-04759 8I

FISH POPULATIONS

Factors Affecting the Recovery of ish Populations in an Industrial River,
W82-04812 5C

Fish Abundance and Distribution Near Three Heated Effluents to Lake Michigan,
W82-05383 5C

Cholinesterase Activity in Estuarine Fishes in the Cumulation of DDT,
W82-05507 5C

Effect of Phenol on In Vivo Activity of Tissue Transaminases in the Fish Notopterus Notopterus,
W82-05571 5C

Histopathological Changes in the Liver and Brain of Fish Exposed to Endosulfan Insecticide During Tsetse Fly Control Operations in Botswana,
W82-05630 5C

FISHERIES

Hypolimnion Oxygenation Studies in Clark Hill Lake,
W82-05001 5G

Fishery Importance of the Ural-Caspian Fishing District and Problems of its Water Supply,
W82-05342 8I

Resolving the Fish vs Flood Control Controversy on the Vedder River,
W82-05765 4A

FIVE-YEAR PLAN

Five-Year Plan for Water Research of the Oklahoma Water Resources Research Institute.
W82-05301 6B

FLOATING ICE

A Mechanism for the formation of Large Icebergs,
W82-04798 2C

Velocity Distributions Under Floating Covers,
W82-05562 2E

FLOCCULATION

New Flocculation Units with High Efficiency,
W82-04840 5D

Filtration Performance in Water and Wastewater Treatment: Theory and Measurement,
W82-05285 5D

Mechanisms and Methods for Polymer Conditioning of Activated Sludge,
W82-05445 5D

Mutual Flocculation of Algae and Clay: Evidence and Implications,
W82-05460 2H

FLOOD CONTROL

New Methods of Designing Flood Control Measures,
W82-05030 2E

Integrated Management of Water Deficits and Floods in a Reservoir System,
W82-05325 4A

Flood Control and Flow Regulation Problems on the Assiniboine River,
W82-05389 4A

Promising Steps Toward a New Ottawa River Regulation,
W82-05394 6E

Resolving the Fish vs Flood Control Controversy on the Vedder River,
W82-05765 4A

Flood Damage Assessment and Flood Control Planning as Part and Parcel of the Economics of Water Utilization (Vloedskadebepaling en Vloedskadebeheer as Onderdele Van Die Ekonomie Van Waterbenutting),
W82-05896 6A

FLOOD DAMAGE

The Overtopping of the Palagnedra Dam,
W82-04952 8A

Flood of July 1-5, 1978 on the Kickapoo River, Southwestern Wisconsin,
W82-05236 2E

Flood of April 12-13, 1979 in Tuscaloosa and Northport, Alabama,
W82-05824 2E

FLOOD DATA

Hydrologic Analysis of Pearl River Floods, April 1979 and April 1980, in Louisiana and Mississippi,
W82-05216 2E

FLOOD DISCHARGE

Flood of July 1-5, 1978 on the Kickapoo River, Southwestern Wisconsin,
W82-05236 2E

FLOOD FORECASTING

Cyclic Fluctuations in the Flood Area and Relationship with the Double (Hale) Sunspot Cycle,
W82-04896 2A

FLOOD FREQUENCY

Investigations of Catastrophic Maximum Discharges of the Araks River,
W82-05591 2E

FLOOD HYDROGRAPHS

An Analysis of Medium and Long Duration Extreme Rainfalls in the Southern Cape Coastal Lakes Region for the Purposes of Flood Hydrograph Generation,
W82-05899 2A

FLOOD INSURANCE

Floodplain Analysis, Simplified vs. Complex Methods: A Case Study,
W82-05732 4A

FLOOD PEAK

Hydrologic Analysis of Pearl River Floods, April 1979 and April 1980, in Louisiana and Mississippi,
W82-05216 2E

Floods of September 16, 1975 in Tallaboa Valley, Puerto Rico,
W82-05230 6F

Flood Peak Regionalization Using Mixed-Mode Estimation of the Parameters of the Log-Normal Distribution,
W82-05495 2E

Estimation of Flood Peaks with Limited Hydrologic Data,
W82-05521 2A

Storm Runoff from Small Lowland Catchments in Southwest England,
W82-05653 4C

FLOOD PEAKS
Peak Runoff Model Comparison on Central Illinois Watersheds,
W82-05489 2A

FLOOD PLAIN MANAGEMENT
Floods of September 16, 1975 in Tallaboa Valley, Puerto Rico,
W82-05230 6F

Floodplain Analysis, Simplified vs. Complex Methods: A Case Study,
W82-05732 4A

FLOOD PLAINS
A Floodplain Storage Model Used to Determine Evaporation Losses in the Upper Yobe River, Northern Nigeria,
W82-04863 2D

The Ecology of Bottomland Hardwood Swamps of the Southeast: A Community Profile,
W82-05054 6G

Water Resources in the Legislative Balance, 1982,
W82-05433 6E

Preliminary Model of an Urban Floodplain Under Changing Land Use,
W82-05642 4C

Flood Hazard Maps as Public Information: An Assessment Within the Context of the Canadian Flood Damage Reduction Program,
W82-05729 7C

FLOOD PROFILES
Floodplain Analysis, Simplified vs. Complex Methods: A Case Study,
W82-05732 4A

FLOODS
A New Method of Cubature Using Spline Functions,
W82-05189 2L

Hydrologic Analysis of Pearl River Floods, April 1979 and April 1980, in Louisiana and Mississippi,
W82-05216 2E

Flood and Debris Flood Hazards Map, Carson City Quadrangle,
W82-05217 7C

Floods of September 16, 1975 in Tallaboa Valley, Puerto Rico,
W82-05230 6F

Flood of July 1-5, 1978 on the Kickapoo River, Southwestern Wisconsin,
W82-05236 2E

Flood of April 12-13, 1979 in Tuscaloosa and Northport, Alabama,
W82-05824 2E

FLOODS FREQUENCY
Floods of September 16, 1975 in Tallaboa Valley, Puerto Rico,
W82-05230 6F

FLOODWATER
Effect of the Spring Flood Regime on the Development of North Casplan Zoobenthos,
W82-05596 2E

FLORIDA
Thermal Regimes of Florida Lakes, A Comparison with Biotic and Climatic Transitions,
W82-04943 2H

Hydrogeologic Data Collected from the Kissimmee Planning Area, South Florida Water Management District,
W82-04974 7C

Hydrologic Description of Lake Jackson, Sebring, Florida,
W82-04975 7C

Hydrology of the Winter Haven Chain of Lakes, Polk County, Florida,
W82-04977 7C

Sinkhole Development Resulting from Ground-Water Withdrawal in the Tampa Area, Florida,
W82-04982 2F

Diel Variations of Certain Physico-Chemical Parameters of Water in Selected Aquatic Systems,
W82-05097 2H

Algal Conditions in the Caloosahatchee River (1975-79) Lake Okeechobee to Franklin Lock, Florida,
W82-05222 5C

Results of Deep-Well Injection Testing at Mulberry, Florida,
W82-05224 5B

The Utilization of Grass Carp, Ctenopharyngodon Idella Val., for Hydrilla Control in Lake Baldwin, Florida,
W82-05274 4A

Aquifer Management in Dade County,
W82-05784 5G

Chloride and Total Hardness Concentrations of Water From the Upper Part of the Floridan Aquifer in St. Johns County, Florida,
W82-05829 7C

Hydrogeologic Sections Through Lee County and Adjacent Areas of Hendry and Collier Counties, Florida,
W82-05830 7C

Potentiometric Surface of the Floridan Aquifer, Southwest Florida Water Management District, September 1981,
W82-05840 7C

Computer Simulation of the Steady-State Flow System of the Tertiary Limestone (Floridan) Aquifer System in East-Central Florida,
W82-05844 2F

Potentiometric Surface of the Floridan Aquifer in the St. Johns River Water Management District and Vicinity, Florida, September 1981,
W82-05849 7C

Potentiometric Surface of the Floridan Aquifer in Central Sumter County, Florida, September 1981,
W82-05850 7C

FLOTATION
Ion-Precipitate Flotation of Iron-Cyanide Complexes,
W82-05259 5D

Foam Fractionation-Flotation as Partial Pretreatment for Reverse Osmosis,
W82-05290 3A

Treatment of Water from Eutrophied Impoundments,
W82-05368 5F

FLOW
Disequilibrium Profile of the Potomac River Near Washington, D.C. - A Result of Lowered Base Level or Quaternary Tectonics Along the Fall Line,
W82-05134 2E

FLOW CHARACTERISTICS
Maximum Pressure During Water Hammer Accompanied by Discontinuity of the Flow,
W82-04772 8B

Calculation of Local Scour of Rock Foundations by High-Velocity Flows,
W82-04775 8B

The Rotating Hydraulics of the Open-Channel Flow Between Two Basins,
W82-05083 8B

The Properties of the Kernels of the Volterra Series Describing Flow Deviations from a Steady State in an Open Channel,
W82-05525 2E

FLOW CONTROL
Water Hammer,
W82-05432 8C

FLOW DISCHARGE
Stochastic Analyses and Transfer Functions for Flows of the Upper Delaware River,
W82-05186 2E

FLOW MEASUREMENT
Try Chemical Tests If Industrial Wastes Are Strong,
W82-05037 5D

On Measuring Time-Averaged Velocities in Open Channel Flow,
W82-05462 2J

FLOW PATTERN
Fluid Flow Pattern in Upflow Reactors for Anaerobic Treatment of Beet Sugar Factory Wastewater,
W82-05372 5D

FLOW PROFILE
Contaminant Dispersion in Oscillatory Flows,
W82-05631 5B

FLOW PROFILES
Circular Wall Jets in Coflowing Streams,
W82-04999 5B

Dispersion in Tumbling Flow,
W82-05796 8B

Flow Under Weir on Scoured Bed,
W82-05800 8B

FLOW RATES
Estimating Water Flow Under Gates,
W82-05514 8B

Discharge Data at Water-Quality Monitoring Stations in Arkansas, 1980 Water Year,
W82-05841 7C

FLOW RESISTANCE
Resistance of Beauharnois Canal in Winter,
W82-04998 2C

Flow Resistance in Wide Rectangular Channels,
W82-05798 8B

FLOW VELOCITY
Ultrasonic Sensors for Monitoring Flows and Sludge Solids Concentrations in Water and Waste-Water Treatment,
W82-04842 5D

Circular Wall Jets in Coflowing Streams,
W82-04999 5B

Discharge Capacity of Large Streams Under an Ice Cover,
W82-05106 2E

Hydraulic Calculations of Stable Unlined Canals by the Vertical Velocity Distribution Method,
W82-05108 8A

Formation of a Stable Canal Channel,
W82-05584 8B

Subsurface Flow Velocities Through Selected Forest Soils, South Island, New Zealand,
W82-05712 4C

FLUCTUATIONS
Bed Load Fluctuation: Applications,
W82-05000 2J

FLUID MECHANICS
Theoretical and Experimental Studies on Dynamic Structure-Fluid Coupling,
W82-04755 8B

The Rotating Hydraulics of the Open-Channel Flow Between Two Basins,
W82-05083 8B

A Laboratory and Theoretical Study of the Boundary Layer Adjacent to a Vertical Melting Ice Wall in Salt Water,
W82-05084 2C

Steady Shallow Flow Over a Spillway,
W82-05086 8B

Finite-Amplitude Stability of Axisymmetric Pipe Flow,
W82-05087 8B

Several Plume Flows in Pure and Saline Water at Its Density Extremum,
W82-05088 2E

A Note on the Structure of the Head of an Intrusive Gravity Current,
W82-05089 2E

Survey of Present Knowledge on Cavitation in Liquids Other Than Cold Water (Thermodynamic Effect),
W82-05280 8B

FLUORESCENCE
Composition and Distribution of Dissolved Fluorescent Substances in the Ems-Dollart Estuary,
W82-04752 2L

Fluorescence Cell Design and Use to Determine Crude Oil in Water,
W82-05358 5A

Use of Algal Fluorescence for an Automated Biological Monitoring System,
W82-05728 5A

FLUORIDES
Determination of Ultratrace Levels of Fluorine in Water and Urine Samples by a Gas Chromatographic/Atmospheric Pressure Helium Microwave Induced Plasma Emission Spectrometric System,
W82-05359 5A

Geochemical Environments and the Geographical Distribution of Some Diseases in Sri Lanka,
W82-05463 5C

FLUSHING MEADOWS PROJECT
Rapid-Infiltration Research at Flushing Meadows Project, Arizona,
W82-05334 5D

FOAM SEPARATION
Foam Fractionation-Flotation as Partial Pretreatment for Reverse Osmosis,
W82-05290 3A

FOAMING
Start-Up Problems of Sludge Dewatering Facility,
W82-05444 5D

FOOD CHAINS
Metabolic Activity of Herbivorous Zooplankton in Lake Kinneret (Israel) During 1972-1977,
W82-05074 2H

FORAGES
Forage Production Utilizing Cheese Plant Effluent Under High-Altitude Conditions,
W82-05265 3C

FORECASTING
Competition for Water Resources: Coal and Agriculture in the Yellowstone Basin,
W82-04805 6D

Consequences and Responsibilities in Drought Forecasting: The Case of Yakima, 1977,
W82-05082 2E

FOREST FIRES
Slash Burning Effects on Soil and Water Chemistry in Southeastern Alaska,
W82-05715 4C

FOREST HYDROLOGY
A Review of Catchment Experiments to Determine the Effect of Vegetation Changes on Water Yield and Evapotranspiration,
W82-05647 4C

Potential Sediment Production Within Vegetative Communities in Oregon's Blue Mountains,
W82-05867 2J

FOREST MANAGEMENT
Seasonal Stream Temperature Changes Following Forest Harvesting,
W82-04870 4C

Forest Management for Increased Water Yield--How Useful in Southern Alberta,
W82-05760 3B

FOREST SOILS
How Much Sewage Nitrogen on Forest Soils. A Case History,
W82-05371 5E

FOREST WATERSHEDS
Effects of Sulfuric Acid Rain on Major Cation and Sulfate Concentrations of Water Percolating Through Two Model Hardwood Forests,
W82-04872 5C

Impact of Hexazinone on Invertebrates After Application to Forested Watersheds,
W82-05206 5C

Sulfate Budget and Model for Sulfate Concentrations in Stream Water at Birkenes, a Small Forested Catchment in Southernmost Norway,
W82-05288 2K

FOULING
Uprating Sludge Digesters by Improving the Heat Transfer of Heatamix Units,
W82-05405 5D

FOUNDATION FAILURE
$12.6 M Repairs Bill for Ruahihi Canal.
W82-05880 8D

FOUNDATION ROCKS
Experience in Preparing the Rock Foundation of the Dnestr Hydroelectric Station,
W82-05585 8H

FRANCE
Centralized Control of the Water Supply Complex for the Marseilles Urban Area (Controle Centralise du Complexe D'Alimentation en Eau De L'Agglomeration de Marseille),
W82-04766 5F

Development of Water Treatment in France (Evolution dans le Traitement des Eaux en France: Quelques Exemples d'Actualite),
W82-05367 5F

Generating Power from Compensating Flow.
W82-05624 8C

FRASER RIVER
Variation in Fecal Pollution Indicators Through Tidal Cycles in the Fraser River Estuary,
W82-05384 5A

The Uncertain Quest for a Management Strategy in the Fraser Estuary,
W82-05392 6F

FRAZIL ICE
Winter Heat Budget and Frazil Ice Production in the Upper St. Lawrence River,
W82-05736 2C

FREEZING
Estimation of Moisture Exchange of Groundwater with Rocks of the Zone of Aeration in the Winter and Spring,
W82-05043 2G

FREQUENCY ANALYSIS
Revised Rainfall Frequency Analysis for Houston,
W82-05863 2B

FROUDE NUMBER
Erosion by Submerged Circular Jets,
W82-05002 2J

Thermal Front Formation from Buoyant Surface Jets,
W82-05004 5C

FROZEN GROUND
Configuration of Ice in Frozen Media,
W82-05615 2C

FULLY PENETRATING WELLS
Cavity Well,
W82-04920 8A

FULVIC ACIDS
Effects of Salts on Activated Carbon Adsorption of Fulvic Acids,
W82-05667 5F

FUNGI
Protein Recovery from Dairy Industry Wastes with Aerobic Biofiltration,
W82-05497 5D

FURROW DRAINAGE
Advance and Runoff-Surge Flow Furrow Irrigation,
W82-05690 3F

GALVANIZED STEEL
Galvanized Steel Stalls Treatment Plant Corrosion,
W82-05167 8G

GAMMA RADIATION
Direct Snow-Water Equivalent Measurements by Air-Borne Gamma-Ray Spectrometry,
W82-05643 2C

GAS CHROMATOGRAPHY
Gas Chromatographic Determination of Phenolic Compounds in Water, as their Pentafluorobenzoyl Derivatives,
W82-04816 5A

Analysis of PCBs in Sediment by Glass Capillary Gas Chromatography,
W82-04916 5A

Determination of Ultratrace Levels of Fluorine in Water and Urine Samples by a Gas Chromatographic/Atmospheric Pressure Helium Microwave Induced Plasma Emission Spectrometric System,
W82-05359 5A

GAS CHROMATOGRPHY
Direct Analytical Method for Aromatic Compounds in Water by Steam Carrier Gas Chromatography,
W82-05164 5A

GASTROPODS
Rare and Endangered Species: Freshwater Gastropods of Southern New England,
W82-04968 5C

GATES
Estimating Water Flow Under Gates,
W82-05514 8B

GEOCHEMISTRY
The Occurrence and Origin of Methane in Some Groundwater Flow Systems,
W82-04925 2K

Geochemical Analysis of the State Drinking Water Standard Gost 2874-73 and Ways to Improve It,
W82-05025 5D

Chemical Constraints of Groundwater Management in the Yucatan Peninsula, Mexico,
W82-05650 4B

The Origin of High Iron Concentrations in Groundwater From the Triassic Aquifer in East Devon,
W82-05801 2K

GEOHYDROLOGIC UNITS
Lineboro Quadrangle: Hydrogeology,
W82-04969 7C

Littletown Quadrangle: Hydrogeology,
W82-04984 7C

GEOHYDROLOGY
Hydrogeologic Data Collected from the Kissimmee Planning Area, South Florida Water Management District,
W82-04974 7C

Hydrogeology for Land-Use Planning: The Potter Creek Area, Anchorage, Alaska,
W82-04981 5G

Structure and Permeability: Geologic Controls on Induced Seismicity at Nurek Reservoir, Tadjikistan, USSR,
W82-05133 2F

Ground-Water Hydrology Around Salt Domes in the East Texas Basin: A Practical Approach to the Contaminant Transport Problem,
W82-05202 5B

Test-Hole Data for the Edwards Aquifer in the San Antonio Area, Texas,
W82-05218 7C

Quality of Ground Water in Routt County, Northwestern Colorado,
W82-05227 2F

An Evaluation of the Effectiveness of Combining Economic and Physical Ground-Water Models,
W82-05545 2F

Cape Cod Aquifer, Cape Cod, Massachusetts,
W82-05807 2F

Hydrogeologic Reconnaissance of the Republican River Basin in Nebraska,
W82-05828 7C

Hydrogeologic Sections Through Lee County and Adjacent Areas of Hendry and Collier Counties, Florida,
W82-05830 7C

Ground-Water Reconnaissance of Part of the Lower Kenai Peninsula, Alaska,
W82-05837 2F

GEOKCHAI RIVER
Calculation of Large Unlined Canals,
W82-05131 8B

GEOLOGIC FISSURES
Evidence for a Shallow Highly-Permeable Zone in the Chalk of Hampshire, U.K.,
W82-05645 2F

GEOLOGIC FORMATIONS
Structure and Permeability: Geologic Controls on Induced Seismicity at Nurek Reservoir, Tadjikistan, USSR,
W82-05133 2F

Disequilibrium Profile of the Potomac River Near Washington, D.C. - A Result of Lowered Base Level or Quaternary Tectonics Along the Fall Line,
W82-05134 2E

GEOLOGICAL SURVEYS
Site Investigation and Materials Save Money on Sallente.
W82-05878 8A

GEOMORPHOLOGY
Sawmill Brook: An Example of Rapid Geomorphic Change Related to Urbanization,
W82-05276 4C

Quantitative Geomorphology of Drainage Basins in Sumter National Forest, South Carolina,
W82-05839 2A

GEOPHYSICS
Structure and Permeability: Geologic Controls on Induced Seismicity at Nurek Reservoir, Tadjikistan, USSR,
W82-05133 2F

GEORGIA
Impact of Hexazinone on Invertebrates After Application to Forested Watersheds,
W82-05206 5C

A Preliminary Appraisal of the Effects of Agriculture on Stream Quality in Southwest Georgia,
W82-05229 5C

Retention of Urban Derived Phosphorus by an Alluvial Swamp of the Coastal Plain of Georgia,
W82-05286 5B

Effects of Waterhyacinth on the Physicochemistry of a South Georgia Pond,
W82-05809 5C

GEOTHERMAL POWER
Geothermal Power: Accidental Fluid Releases and Waste Disposal,
W82-04911 5B

An Assessment of Geothermal Development in the Imperial Valley of California; Volume 2 - Environmental Control Technology,
W82-05213 5E

An Assessment of Geothermal Development in the Imperial Valley of California; Volume 1 - Environment, Health and Socio-economics,
W82-05214 6G

GEOTHERMAL RESOURCES
An Assessment of Geothermal Development in the Imperial Valley of California; Volume 2 - Environmental Control Technology,
W82-05213 5E

An Assessment of Geothermal Development in the Imperial Valley of California; Volume 1 - Environment, Health and Socio-economics,
W82-05214 6G

GEOTHERMAL STUDIES
A Derivation of the Equations for Transport of Liquid and Heat in Three Dimensions in a Fractured Porous Medium,
W82-04888 2F

Possibility of Substantiating the Groundwater Flow Equation on the Basis of Thermodynamics of Irreversivble Processes,
W82-05032 2F

Fluorapatite and Fluorite Solubility Controls on Geothermal Waters in Yellowstone National Park,
W82-05449 2K

GERMAN BIGHT
The Tidal Stream in the German Bight,
W82-05190 2L

GERMANY
Automatic Control of the Discharge of Radioactive Subsubstances from Light Water Nuclear Power Plants of the Pressurized Water Reactor Type into Flowing Streams with Special Reference to the Unterweser Nuclear Power Plant,
W82-04839 5E

Nutrient Distribution in North German Lake Sediments and Remarks on Sediment-Pelagic Exchange (Die Nahrstoffverteilung in Sedimenten Norddeutscher Seen und Hinweise Auf Den Austausch Sediment-Pelagial),
W82-05091 2H

Disposing of Sewage Sludge at Sea,
W82-05127 5E

Experiences with Purification Lakes and Polishing Lagoons,
W82-05241 5D

Northern Elbe Culvert,
W82-05427 8B

GETTYSBURG FORMATION
Groundwater Resources of the Gettysburg and Hammer Creek Formations, Southeastern Pennsylvania,
W82-04973 2F

GILA RIVER BASIN
Nitrogen and Phosphorus Dynamics in Hot Desert Streams of Southwestern U.S.A.,
W82-04930 2K

GLACIAL AQUIFERS
Ground-Water Reconnaissance of Part of the Lower Kenai Peninsula, Alaska,
W82-05837 2F

GLACIAL LAKES
The Structure of Crustacean Zooplankton Communities in Glaciated Eastern North America,
W82-05379 2H

GLACIERS
Glaciers and Their Fluctuations,
W82-04777 2C

GLATT RIVER
Persistent Organic Chemicals in Sewage Effluents: I. Identifications of Nonylphenols and Nonylphenolethoxylates by Glass Capillary Gas Chromatography/Mass Spectrometry,
W82-04834 5A

GRAIN CROPS
Flexcrop: A Dryland Cropping Systems Model,
W82-05208 3F

GRAPHICAL ANALYSIS
Using Pump Curves and Valving Techniques for Efficient Pumping,
W82-05666 8C

GRAVEL
Stable-Channel Design in Gravel-Bed Rivers,
W82-04865 2E

Bedload and Size Distribution in Paved Gravel-Bed Streams,
W82-05795 2J

GRAVITY DAMS
Safety Analysis of High Hazard Deteriorating Concrete Gravity Dam-Reservoir Systems Including Corrective Measure - Earthquake and Dynamic Study,
W82-05296 8A

GRAVITY DAMS

Selecting the Optimum Cross-Section of a Concrete Gravity Dam,
W82-05510 8A

GRAVITY FLOW
Possibility of Substantiating the Groundwater Flow Equation on the Basis of Thermodynamics of Irreversivble Processes,
W82-05032 2F

GRAVITY STUDIES
A Note on the Structure of the Head of an Intrusive Gravity Current,
W82-05089 2E

GRAZING
Plant Improvement for Semi-Arid Rangelands: Possibilities for Drought Resistance and Nitrogen Fixation,
W82-05610 3F

GREASE
Oil and Grease in Stormwater Runoff,
W82-05557 5C

GREAT BRITAIN
The Search for Reservoir Sites in an Urban Environment,
W82-04867 8A

Experimental Studies to Determine the Fate of Petroleum Hydrocarbons from Refinery Effluent on an Estuarine System,
W82-05144 5B

The Transport to and Deposition of Americium in Intertidal Sediments of the Ravenglass Estuary and its Relationship to Plutonium,
W82-05178 5B

GREAT LAKES
A Preliminary Assessment of Michigan's Phosphorus Detergent Ban,
W82-04786 5G

Quantification of Octachlorostyrene and Related Compounds in Great Lakes Fish by Gas Chromatography-Mass Spectrometry,
W82-04993 5A

Effects of Increased Atmospheric C02 on Great Lakes,
W82-05209 2H

A Survey of Phosphorus Removal in Lower Great Lakes Municipal Treatment Plants,
W82-05256 5D

Determination of Mutagenic Potential and Organic Contaminants of Great Lakes Drinking Water,
W82-05398 5A

Organochlorine Residues in Suspended Solids Collected from the Mouths of Canadian Streams Flowing into the Great Lakes 1974-1977,
W82-05635 5B

GREAT LAKES TRIBUTARIES
Algal-Available Phosphorus in Suspended Sediments from Lower Great Lakes Tributaries,
W82-04994 5B

GREAT MARSH
Sulfur Speciation and Associated Trace Metals (FE, CU) in the Pore Waters of Great Marsh, Delaware,
W82-05415 2K

GREAT MAZURIAN LAKES
Epilimnetic and Hypolimnetic Symptoms of Eutrophication in Great Mazurian Lakes, Poland,
W82-05103 2H

GREAT SALT LAKE DESERT
Hydrologic Reconnaissance of the Southern Great Salt Lake Desert and Summary of the Hydrology of West-Central Utah,
W82-05221 7C

GREAT SMOKY MOUNTAINS NATIONAL PARK
Toxicity of Anakeesta Formation Leachates to Shovel-Nosed Salamander, Great Smoky Mountains National Park,
W82-04988 5C

GREAT STAVROPOL CANAL
Use of Watertight Film Facings for Repair Works on the Great Stavropol Canal,
W82-05117 8G

GREEN RIVER
Ecological Effects of Urban Stormwater Runoff on Benthic Macroinvertebrates Ihibiting the Green River, Massachusetts,
W82-04947 5C

GREEN RIVER BASIN
Derivation of Homogeneous Streamflow Records for the Green River Basin, Kentucky,
W82-04979 2E

GROUNDWATER

GROUNDWATER MANAGEMENT
Advanced Wastewater Treatment for Groundwater Recharge--Berlin Recharge Project (Recyclage et Traitement D'Eaux usees pour Recharger une nappe Souterraine: L'Installation Pilote de Berlin),
W82-04831 5D

Barriers to Effective Ground-Water Management: The California Case,
W82-04917 4B

The Potential for Ground-Water Management in the West: A Symposium,
W82-04918 4B

Ground-Water Network Design for Northwest Kansas, Using the Theory of Regionalized Variables,
W82-04921 4B

Economics of Declining Water Supplies in the Ogallala Aquifer,
W82-04922 4B

Ground-Water Management in Basalts,
W82-04931 4B

Ground-Water Development in Western River Basins: Large Economic Gains with Unseen Costs,
W82-04932 4B

Arizona Ground-Water Reform: Innovations in State Water Policy,
W82-04933 6E

Regional Management of Groundwater Recharge and Pollution in a Rapidly Urbanizing Area: Long Island, N.Y.,
W82-04956 4B

The Status of Groundwater Law in New York State,
W82-05400 6E

Five Year Water Resources Research Plan for the State of California,
W82-05532 6B

Efficient Water Use in California: Conjunctive Management of Ground and Surface Reservoirs,
W82-05628 4B

Chemical Constraints of Groundwater Management in the Yucatan Peninsula, Mexico,
W82-05650 4B

GROUNDWATER MINING
Barriers to Effective Ground-Water Management: The California Case,
W82-04917 4B

How Proper Prospecting Improves the Odds,
W82-05757 3B

The Hydrogeological Basis for a Water Supply to Kabwe, Zambia,
W82-05804 4B

The Physical Environment of the Colorado River Basin,
W82-05891 6D

GROUNDWATER MOVEMENT
A Derivation of the Equations for Transport of Liquid and Heat in Three Dimensions in a Fractured Porous Medium,
W82-04888 2F

Possibility of Substantiating the Groundwater Flow Equation on the Basis of Thermodynamics of Irreversivble Processes,
W82-05032 2F

An Evaluation of the Effectiveness of Combining Economic and Physical Ground-Water Models,
W82-05545 2F

Numerical Simulation of a Thick Freshwater Lens: Pearl Harbor Groundwater Model,
W82-05621 2F

Computer Simulation of the Steady-State Flow System of the Tertiary Limestone (Floridan) Aquifer System in East-Central Florida,
W82-05844 2F

GROUNDWATER POLLUTION
Groundwater Monitoring,
W82-04809 6E

The Occurrence of Flow Channels in Soils,
W82-04875 3C

The New Pollution--Groundwater Contamination,
W82-04938 5C

Pilot Field Studies of FGD Waste Disposal at Louisville Gas and Electric,
W82-05066 5E

Empirical Test of the Association Between Gross Contamination of Wells with Toxic Substances and Surrounding Land Use,
W82-05143 5B

Ground-Water Hydrology Around Salt Domes in the East Texas Basin: A Practical Approach to the Contaminant Transport Problem,
W82-05202 5B

Optimal Dynamic Management of Groundwater Pollutant Sources,
W82-05345 5G

Determination of Metals in Groundwaters by Trace Enrichment and Liquid Chromatography,
W82-05361 5A

Groundwater Pollution Investigations in the Great Ouse Basin,
W82-05475 5B

Optimal Location and Management of Waste Disposal Facilities Affecting Ground Water Quality,
W82-05740 5G

Occurrence of Endotoxins in Groundwater During the Land Application of Wastewater,
W82-05810 5B

GROUNDWATER RECHARGE
Advanced Wastewater Treatment for Groundwater Recharge--Berlin Recharge Project (Recyclage et Traitement D'Eaux usees pour Recharger une nappe Souterraine: L'Installation Pilote de Berlin),
W82-04831 5D

Assessment of a Regional Aquifer in Central Illinois,
W82-05052 2F

Chemical Character of Water in the Red River Alluvial Aquifer, Louisiana,
W82-05228 7C

The Likelihood of Active Groundwater Recharge in the Botswana Kalahari,
W82-05657 4B

Potential for Groundwater Recharge Seepage from Flood-Retarding Reservoirs in South Central Nebraska,
W82-05663 4B

GROUNDWATER STORAGE
Ground-Water Management in Basalts,
W82-04931 4B

GROUTING
Quantitative Relationship of Grouting to the Reduction of Groundwater Flow Through Rock Foundations,
W82-05201 8E

GROWTH RATES
The Effect of Phosphorus Limitation on Algal Growth Rates: Evidence from Alkaline Phosphatase,
W82-05380 5C

GROWTH STAGES
Improved Water and Nutrient Management Through High-Frequency Irrigation, Vol 2: Response of Peanuts to Irrigation Management at Different Crop Growth Stages,
W82-05293 3F

GUAM
Metal Concentrations in Guam Urban Runoff,
W82-05302 5B

The Effects of Land-Clearing on a Small Watershed in Southern Guam,
W82-05303 5C

Water Quality Assessment for Agana Springs,
W82-05304 5A

Ammonium Uptake by Micronesian Species of Gracilaria (Rhodophyta),
W82-05311 5G

HABITATS
Wetlands and Deepwater Habitats: A New Classification,
W82-05716 2L

HALIFAC
Factors Affecting Coliform Bacteria Growth in Distribution systems,
W82-04792 5F

HALOGENATED PESTICIDES
Selected Organic Pesticides, Behavior and Removal from Domestic Wastewater by Chemical and Physical Processes,
W82-05481 5D

HALOGENS
Comparison of Trihalomethane Levels and Other Water Quality Parameters for Three Treatment Plants on the Ottawa River,
W82-04810 5F

HAMBURG
Northern Elbe Culvert,
W82-05427 8B

HAMMER CREEK FORMATION
Groundwater Resources of the Gettysburg and Hammer Creek Formations, Southeastern Pennsylvania,
W82-04973 2F

HAWAII
Numerical Simulation of a Thick Freshwater Lens: Pearl Harbor Groundwater Model,
W82-05621 2F

Summary of Available Data on Surface Water, State of Hawaii. Volume I: Island of Kauai,
W82-05836 7C

HAZARDOUS MATERIALS
Weak Controls from Sea to Shining Sea,
W82-05035 5B

Removal of Water Soluble Hazardous Materials Spills from Waterways by Activated Carbon,
W82-05060 5G

Use of Selected Sorbents and an Aqueous Film Foam on Floating Hazardous Materials,
W82-05063 5G

Feasibility of Commercialized Water Treatment Techniques for Concentrated Waste Spills,
W82-05068 5G

A Mobile Stream Diversion System for Hazardous Materials Spills Isolation,
W82-05070 5G

Biological Monitoring of Hazardous Wastes in Aquatic Systems,
W82-05154 5A

Bioprobes for the Monitoring of Toxic Compounds and Hazardous Materials in Water,
W82-05161 5A

Microbial Removal of Hazardous Organic Compounds,
W82-05177 5D

Seasonal Risk-Based Reservoir Operating Rules,
W82-05299 4A

HAZARDS
Flood and Debris Flood Hazards Map, Carson City Quadrangle,
W82-05217 7C

Safety Considerations in Handling Activated Carbon,
W82-05442 5D

HEAT BUDGET
Winter Heat Budget and Frazil Ice Production in the Upper St. Lawrence River,
W82-05736 2C

HEAT EXCHANGERS
An Evaluation of Twin Wells for Use with Water Source Heat Pumps,
W82-05307 8B

Use of Twin Wells and Water-Source Heat Pumps for Energy Conservation in Louisiana,
W82-05535 8B

HEAT FLOW
Heat Loss from Rapid Infiltration Basin in Winter,
W82-05317 5D

HEAT TRANSFER
A Derivation of the Equations for Transport of Liquid and Heat in Three Dimensions in a Fractured Porous Medium,
W82-04888 2F

Surface Heat Fluxes from Lake Ontario: Further Verification of Lake Thermal Model,
W82-05048 2H

An Evaluation of Twin Wells for Use with Water Source Heat Pumps,
W82-05307 8B

Uprating Sludge Digesters by Improving the Heat Transfer of Heatamix Units,
W82-05405 5D

Use of Twin Wells and Water-Source Heat Pumps for Energy Conservation in Louisiana,
W82-05535 8B

HEAT TREATMENT
Improved Thermal Sludge Conditioning by Treatment with Acids and Bases,
W82-04785 5E

HEAVY METALS
Chemical Fractionation of Heavy Metals in Wastewater-Affected Soils,
W82-04781 5B

Anodic Stripping Voltammetry as an Analytical Tool,
W82-04811 5A

Pixe Trace Element Analysis of an Aquatic Plant as Indicator of Heavy Metal Pollution,
W82-04818 5A

Effect of Mixed Liquor Suspended Solids Concentration on the Biodegradation of Nitrilotriacetic Acid in the Activated Sludge Process,
W82-04829 5C

Uptake of Arsenic, Cadmium, Lead and Mercury from Polluted Waters by the Water Hyacinth Eichornia Crassipes,
W82-04936 5B

Speciation of Copper and Manganese in Effluents from the Activated Sludge Process,
W82-04937 5D

The Effects of Dissolved Heavy Metals on Attached Diatoms in the Uintah Basin of Utah, U.S.A.,
W82-04951 5A

Data Base for Influent Heavy Metals in Publicly Owned Treatment Works,
W82-05056 5D

Heavy Metal Sources and Flows in a Municipal Sewage System: Literature Survey and Field Investigation of the Kokomo, Indiana, Sewage System,
W82-05061 5D

Empirical Test of the Association Between Gross Contamination of Wells with Toxic Substances and Surrounding Land Use,
W82-05143 5B

Influence of Water Movements and Other Factors on Distribution and Transport of Heavy Metals in a Shallow Bay (Canada),
W82-05205 5B

Low Pressure Membrane Separation Process to Remove Heavy Metal Complexes,
W82-05284 5D

Metal Concentrations in Guam Urban Runoff,
W82-05302 5B

Enzyme Activity and Kinetics in Substrate-Amended River Sediments,
W82-05336 5C

Industrial Wastewater Treatment Technology--Recent Developments,
W82-05348 5D

Forms of the Migration of Metallic Ions in Fresh Water,
W82-05456 2K

Manganese, Zinc and Copper in Hydrobionts in the Danube and the Northwestern Black Sea,
W82-05458 5B

The Impact of Acidic Precipitation and Heavy Metals on Soils in Relation to Forest Ecosystems,
W82-05534 5C

A Computer Model for Heavy Metal Transport within the Penobscot River,
W82-05544 5B

Geochemical Pathway Studies of Heavy Metals in Lake Sediments from the Sudbury-Temagami Area, Ontario,
W82-05640 5B

HERBICIDES
Toxicities of Paraquat and Metribuzin (Sencor) Herbicides to the Freshwater Copepods, Eucyclops Agilis and Diaptomus Mississippiensis,
W82-04814 5C

Impact of Hexazinone on Invertebrates After Application to Forested Watersheds,
W82-05206 5C

Trace Enrichment of Difenzoquat in Water and Its Determination by Reversed Phase High Performance Liquid Chromatography,
W82-05362 5A

The Fate of Organic Pollutants in Frozen Waters: Sunlight Photodecomposition of Uracil Herbicides in Frozen Aqueous Solutions,
W82-05479 5B

Selected Organic Pesticides, Behavior and Removal from Domestic Wastewater by Chemical and Physical Processes,
W82-05481 5D

Effects of Waterhyacinth on the Physicochemistry of a South Georgia Pond,
W82-05809 5C

HERSEY RIVER
Movement and Identification of a Creosote-Derived PAH Complex Below a River Pollution Point Source,
W82-05042 5B

HEXACHLOROBENZENE
Elimination of Hexachlorobenzene (HCB) by Rainbow Trout (Salmo Gairdneri), and an Examination of Its Kinetics in Lake Ontario Salmonids,
W82-05195 5B

HIGHWAY EFFECTS
Toxicity of Anakeesta Formation Leachates to Shovel-Nosed Salamander, Great Smoky Mountains National Park,
W82-04988 5C

HISTORIC FLOODS
Investigations of Catastrophic Maximum Discharges of the Araks River,
W82-05591 2E

HISTORY
Anthropogenically Derived Changes in the Sedimentary Flux of Mg, Ni, Cu, Zn, Hg, Pb, and P in Lough Neagh, Northern Ireland,
W82-05145 5B

The River Tame--A Short History of Water Pollution and Control Within an Industrial River Basin,
W82-05242 5C

The Continuing Struggle of Waterborne Illness,
W82-05366 5C

HUMAN DISEASES
Geochemical Environments and the Geographical Distribution of Some Diseases in Sri Lanka,
W82-05463 5C

HUMIC ACIDS
Comparison of Photochemical Behavior of Various Humic Substances in Water: I. Sunlight Induced Reactions of Aquatic Pollutants Photosensitized,
W82-04914 2K

Comparison of Photochemical Behavior of Various Humic Substances in Water: II. Photosensitized Oxygenations,
W82-04915 2K

Metal Ion Complex Formation Constants of Some Sedimentary Humic Acids with Zn(II), Cu(II) and Cd(II),
W82-05136 2K

Organic Groups and Molecular Weight Distribution in Tertiary Effluents and Renovated Waters,
W82-05480 5D

HUMIDITY
Humidity Measurement by Infrared Thermometry,
W82-05611 7B

HUSTON
Comprehensive Analysis of Nitrification of Chemical Processing Wastewaters,
W82-05271 5D

HYDRATION
Ion Hydration and Ion Interaction,
W82-05310 2K

HYDRAULIC CAPACITY
Sludge Management in the Rocky Mountain State,
W82-05165 5E

HYDRAULIC ENGINEERING
Maximum Pressure During Water Hammer Accompanied by Discontinuity of the Flow,
W82-04772 8B

Erosion by Plane Turbulent Jets,
W82-05277 8B

HYDRAULIC FILL
Calculation of the Temperature Regime of Hydraulic Fill Dams During Their Construction,
W82-04760 8D

Damming of the Kara-Bogaz-Gol Strait without Side Diversion of the Flow,
W82-05114 8A

HYDRAULIC JUMP
An Investigation of a Jet-Assisted Hydraulic Jump,
W82-05279 8B

HYDRAULIC MACHINERY
Use and Investigation of Water-Jet Pumps (Ejectors) at the Chirkey Hydroelectric Station,
W82-05592 8C

HYDRAULIC MODELS
Hydraulic Model Studies of Landslide-Generated Water Waves-Morrow Point Reservoir,
W82-05211 8B

HYDRAULIC PROPERTIES
Calculation of Large Unlined Canals,
W82-05131 8B

HYDRAULIC STRUCTURES
Stress State of a Rock Mass with Two Parallel Tunnels with Loading of One of them by a Uniform Internal Pressure,
W82-05116 8E

Dynamic Elastic and Absorbing Properties of Soils,
W82-05132 8D

Driving Large Hydraulic Tunnels by the Stepped Face Method,
W82-05586 8H

Prospective Engineering Designs for Underground Hydraulic Structures,
W82-05589 8A

HYDRAULIC TURBINES
Turbines for Itaipu,
W82-04955 8C

HYDRAULICS
The Rotating Hydraulics of the Open-Channel Flow Between Two Basins,
W82-05083 8B

Reflections of the Choice of Some Priority Axes of Hydraulic Research in the Field of Land and Water Management,
W82-05278 4B

HYDROCARBONS
Fluxes of Polycyclic Aromatic Hydrocarbons to Marine and Lacustrine Sediments in the Northeastern United States,
W82-05138 5B

Extractable Organic Matter in Municipal Wastewaters. I. Petroleum Hydrocarbons: Temporal Variations and Mass Emission Rates to the Ocean,
W82-05142 5B

Volatile Constituents of the Produced Water Effluent from the Buccaneer Gas and Oil Field,

Determination of Metals in Groundwaters by Trace Enrichment and Liquid Chromatography, W82-05361 5A

The Determination of Heavy Metals (Al, Mn, Fe, Ni, Cu, Zn, Cd, and Pb) in Urban Snow Using an Atomic Absorption Graphite Furnace, W82-05397 5A

Sulfur Speciation and Associated Trace Metals (FE, CU) in the Pore Waters of Great Marsh, Delaware, W82-05415 2K

Procedure for Investigating Metallic Ion Complexing in Natural Waters, W82-05595 5A

Effect of Sewage Effluent on the Sediments of Nordasvatnet (A Landlocked Fjord), Norway, W82-05605 5B

METHANE

Comparison of Trihalomethane Levels and Other Water Quality Parameters for Three Treatment Plants on the Ottawa River, W82-04810 5F

The Occurrence and Origin of Methane in Some Groundwater Flow Systems, W82-04925 2K

A System for Measuring Methane Fluxes from Inland and Coastal Wetland Environments, W82-04989 2L

Methane in Water Wells, W82-05262 5F

METHOXYCHLOR

Methoxychlor Residues in Treated Irrigation Canal Water in Southcentral Idaho, W82-05726 5B

METHYL CHLOROFORM

Removal of Refractory Organics from Water by Aeration. I. Methyl Chloroform, W82-05174 5D

METHYLMERCURY

Mercury Circulation in Aquatic Environment. Part 3. Mercury Transformations in Sediments, W82-05094 5B

METROPOLITAN WATER MANAGEMENT

Domestic Water Conservation Research Plan, W82-05547 6B

Water Management in the Metropolitan Toronto Region, W82-05775 6B

MEXICO

Restructuration of the Water Tariff System for Irrigation Districts in Mexico. W82-04962 6C

MEXICO (YUCATAN PENINSULA)

Chemical Constraints of Groundwater Management in the Yucatan Peninsula, Mexico, W82-05650 4B

MICHIGAN

A Preliminary Assessment of Michigan's Phosphorus Detergent Ban, W82-04786 5G

Determination of 2,3,7,8-Tetrachlorodibenzo-P-Dioxin in Fresh Water Fish, W82-04883 5A

A Comparison of Vascular Vegetation and Protozoan Communities in Some Freshwater Wetland of Northern Lower Michigan, W82-04927 2H

Movement and Identification of a Creosote-Derived PAH Complex Below a River Pollution Point Source, W82-05042 5B

Septic Leachate Surveys for Lakeside Sewer Needs Evaluation, W82-05322 5B

Economical and Efficient Phosphorus Control at a Domestic-Industrial Wastewater Plant, W82-05324 5D

Michigan Five-Year Water Resources Research and Development Plan: Fiscal Years 1982-1986. W82-05530 6B

MICROBIAL DEGRADATION

The Dissipation of Nonylphenol in Stream and Pond Water Under Simulated Field Conditions, W82-05273 5B

MICROBIAL TREATMENT

Enhanced Biodegradation of Pesticides in Soil to Alleviate Contaminated Runoff, W82-04967 5G

MICROBIOLOGICAL STUDIES

Initial Microbiological Response in Lakes to the Mt St Helens Eruption, W82-05125 2H

Enzyme Activity and Kinetics in Substrate-Amended River Sediments, W82-05336 5C

An Electron Microscopic Study of the Forms of Bacteria in the Surface Film of the Water, W82-05452 2H

MICROORGANISMS

Ammonium Uptake by Micronesian Species of Gracilaria (Rhodophyta), W82-05311 5G

Radiotracer Experiments on Phosphorus Uptake and Release by Limnetic Microzooplankton, W82-05381 5B

Environmental Impact of the Microbial Aerosol Emissions from Wastewater Treatment Plants, W82-05428 5B

MILWAUKEE

Railroad's Shops Correct an Oily Wastes Problem, W82-05130 5D

MINE DRAINAGE

Acid Pond Drainage, W82-05199 5G

MINE WASTES

Placer Mining and Salmon Spawning in American River Basin, California, W82-05200 8I

Influence of Water Movements and Other Factors on Distribution and Transport of Heavy Metals in a Shallow Bay (Canada), W82-05205 5B

MINERALS

The Effect of Pressure on the Solubility of Minerals in Water and Seawater, W82-05135 1B

Soluble Mineral Content in Surficial Alluvium and Associated Mancos Shale, W82-05751 3B

MIRROW LAKE

Biomass and Annual Production of the Freshwater Mussel Elliptio Complanata in an Oligotrophic Softwater Lake, W82-05104 2H

MISSISSIPPI

Hydrologic Analysis of Pearl River Floods, April 1979 and April 1980, in Louisiana and Mississippi, W82-05216 2E

Quality of Water in James Creek, Monroe County, Mississippi, W82-05842 5B

Quality of Water and Time of Travel in Goodwater and Okatoma Creeks Near Magee, Mississippi, W82-05845 5B

Quality of Water and Time of Travel in Little Copiah Creek near Crystal Springs, Mississippi, W82-05847 5B

MISSISSIPPI RIVER DELTA

The Influence of Water Salinity on Paludal Erosion Processes, W82-04995 2J

MISSOURI

Acid Pond Drainage, W82-05199 5G

Quantitative Relationship of Grouting to the Reduction of Groundwater Flow Through Rock Foundations, W82-05201 8E

Drought-Related Water Conservation Efforts in Missouri, W82-05672 3D

MIXED LIQUOR SOLIDS

Effect of Mixed Liquor Suspended Solids Concentration on the Biodegradation of Nitrilotriacetic Acid in the Activated Sludge Process, W82-04829 5C

MIXING

Circular Wall Jets in Coflowing Streams, W82-04999 8H

Mechanisms and Methods for Polymer Conditioning of Activated Sludge, W82-05445 5D

MMBRANE PROCESSES

Reconnaissance Samplings and Characterization of Aquatic Humic Substances at the Yuma Desalting Test Facility, Arizona, W82-04983 3A

MODEL STUDIES

Modeling: How and When to Use, W82-04754 2L

Dynamic Parameter Tuning for Water Distribution Network Models in an Extended Period Simulation, W82-04756 5F

Application of an Approximate Analytic Method of Computing Solute Profiles with Dispersion in Soils, W82-04876 5B

NUREK RESERVOIR
Structure and Permeability: Geologic Controls on Induced Seismicity at Nurek Reservoir, Tadjikistan, USSR,
W82-05133 2F

NUTRIENT DYNAMICS
Floodwater Nutrient Processing in a Louisiana Swamp Forest Receiving Agricultural Runoff,
W82-05622 5C

Modeling of Phytoplankton-Nutrient Dynamics in Saginaw Bay, Lake Huron,
W82-05639 5C

NUTRIENT REMOVAL
Stream Transport of Nutrients Through a Wetland,
W82-04857 5B

The Effects of Varying Culture Nitrogen and Phosphorus Levels of Nutrient Uptake and Storage by the Waterhyacinth Eichhornia Crassipes (Mart) Solms,
W82-05098 5G

Retention of Urban Derived Phosphorus by an Alluvial Swamp of the Coastal Plain of Georgia,
W82-05286 5B

NUTRIENT REQUIREMENTS
Improved Water and Nutrient Management Through High Frequency Irrigation,
W82-05313 3F

NUTRIENTS
Sediment Water Exchanges of Nutrients and Oxygen on Tidal Flats in the Ems-Dollart Estuary,
W82-04751 2L

Boron Status of Berlin Waters (Bor-Status Berliner Gewasser),
W82-04767 5A

Abiogenic Elimination of Nutrients in a Newly Built Reservoir (Twistetalsperre, Nordhessen) (Abiogene Nahrstoffeliminierung in einer Neuentstandenen Talsperre (Twistetalspherre, Nordhessen),
W82-04768 2H

Stream Transport of Nutrients Through a Wetland,
W82-04857 5B

The Decline of Salvinia Molesta on Lake Kariba,
W82-04945 2H

Mineral Composition of Phragmites Australis in Scottish Lochs as Related to Eutrophication. I. Seasonal Changes in Organs,
W82-05099 2H

Kinetics of Nutrient and Metal Release from Decomposing Lake Sediments,
W82-05139 2H

Plankton Metabolism and Carbon Processes in the Amazon River, Its Tributaries, and Floodplain Waters, Peru-Brazil, May-June 1977,
W82-05197 2K

Forage Production Utilizing Cheese Plant Effluent Under High-Altitude Conditions,
W82-05265 3C

Urban Impacts of Water Supply Reservoir,
W82-05318 5G

Strategies for Maintaining Water Quality in Two British Columbia Lakes,
W82-05567 5G

Run-Off and Infiltration Losses Related to Shifting Agriculture (JHUM) in Northeastern India,
W82-05573 4C

A Case Study of Nutrients in the River Holem, West Yorkshire, England,
W82-05577 5B

Microscale Patchiness of Nutrients in Plankton Communities,
W82-05613 2H

Indications of Ground Water Influences on Nutrient Transport Through Schwatka Lake, Yukon Territory,
W82-05741 5B

Selecting a Method for Estimating Substance Loadings,
W82-05746 5B

Dual Objective Control of Nutrient Loading into a Lake,
W82-05750 5G

OBSERVATION WELLS
Ground-Water Network Design for Northwest Kansas, Using the Theory of Regionalized Variables,
W82-04921 4B

Map Showing the Potentiometric Surface of the Aquia Aquifer, May 19-23, 1980,
W82-04978 7C

OBSERVATIONS
Map Showing how the Potentiometric Surface of the Magothy Aquifer of August 1980 Differed from the Potentiometric Surface of September 1977, in Southern Maryland,
W82-05838 7C

OCEAN CIRCULATION
The Residence Time of the Freshwater Component in the Artic Ocean,
W82-05872 2A

OCEAN DUMPING
Disposing of Sewage Sludge at Sea,
W82-05127 5E

Extractable Organic Matter in Municipal Wastewaters. I. Petroleum Hydrocarbons: Temporal Variations and Mass Emission Rates to the Ocean,
W82-05142 5B

Wastewater Management in Coastal North Carolina,
W82-05559 5E

ODOR CONTROL
How the Tyne Was Saved. Duke of Edinburgh Opens 120 Million Pound Sterling Scheme.
W82-05249 5D

OFFICE OF WATER RESEARCH AND TECHNOLOGY
Water Research in Action.
W82-05292 6B

OGALLALA AQUIFER
Economics of Declining Water Supplies in the Ogallala Aquifer,
W82-04922 4B

OHIO
Computer-Based Implementation of Combined Sewer Control,
W82-04783 5D

Algal Bioassay of the Portage Lakes, Summit County, Ohio,
W82-04813 2H

Water Use in Ohio, 1975,
W82-05226 6D

Assessment of Water Quality in Streams Draining Coal-Producing Areas in Ohio,
W82-05234 5B

Hydrology of Area 4, Eastern Coal Province, Pennsylvania, Ohio, and West Virginia,
W82-05833 7C

OIL
Fluorescence Cell Design and Use to Determine Crude Oil in Water,
W82-05358 5A

Biodegradation of Synthetic Crude Oil in Two Rivers of Northern Alberta, Canada,
W82-05486 5B

OIL INDUSTRY
Petroleum Refinery Wastewater Induction of the Hepatic Mixed-Function Oxidase System in Pacific Staghorn Sculpin,
W82-04895 5C

Shale Oil Wastewater Treatment by Evaporation,
W82-04905 5D

Experimental Studies to Determine the Fate of Petroleum Hydrocarbons from Refinery Effluent on an Estuarine System,
W82-05144 5B

OIL POLLUTION
An Approximate Petroleum Hydrocarbon Budget for the Hudson Raritan Estuary--New York,
W82-05606 5B

OIL RECOVERY
Performance Testing of the Diperna Sweeper,
W82-05058 5G

Performance Testing of Four Skimming Systems,
W82-05059 5G

Deployment Configurations for Improved Oil Containment with Selected Sorbent Booms,
W82-05062 5G

OIL REFINERIES
Designing Wastewater Treatment Systems to Save Energy,
W82-04906 5D

OIL SHALE
Oil Shale and Water Quality: The Colorado Phospectus under Federal, State, and International Law,
W82-04803 6E

Shale Oil Wastewater Treatment by Evaporation,
W82-04905 5D

Fingerprinting Inorganic Arsenic and Organoarsenic Compounds in the Situ Oil Shale Retort and Process Waters Using a Liquid Chromatograph Coupled with an Atomic Absorption Spectrometer as a Detector,
W82-05151 5A

Chronic Effects of Ammonia-Stripped Oil Shale Retort Water on Fishes, Birds, and Mammals,
W82-05375 5C

Cold Lake-Beaver River Regional Water Resources Study,
W82-05396 6D

OIL SHALE MINING
Chronic Effects of Ammonia-Stripped Oil Shale Retort Water on Fishes, Birds, and Mammals,
W82-05375 5C

OIL SKIMMERS
Performance Testing of the Diperna Sweeper,
W82-05058 5G

Performance Testing of Four Skimming Systems,
W82-05059 5G

OIL SLICKS
Oil Slick Mechanics,
W82-05064 5G

OIL SPILLS
Effect of Long Term Exposure to Petroleum on Mixed Function Oxygenases in Fish: Further Support for Use of the Enzyme System in Biological Monitoring,
W82-04884 5C

Deployment Configurations for Improved Oil Containment with Selected Sorbent Booms,
W82-05062 5G

Oil Slick Mechanics,
W82-05064 5G

Dispersant Application System for the U.S. Coast Guard 32-Foot WPB,
W82-05069 5G

Handbook for Oil Spill Protection and Cleanup Priorities,
W82-05210 5G

OIL WASTES
Mutagenic Potential of Water Concentrates from the Effluent of a Waste Oil Storage Pond,
W82-05727 5C

OIL-WATER INTERFACES
Oil Slick Mechanics,
W82-05064 5G

OILY WATER
Oil and Grease in Stormwater Runoff,
W82-05557 5C

OKLAHOMA
Economics of Declining Water Supplies in the Ogallala Aquifer,
W82-04922 4B

Five-Year Plan for Water Research of the Oklahoma Water Resources Research Institute.
W82-05301 6B

ONONDAGA
Characterization of Industrial Wastes by Evaluating BOD, COD, and TOC,
W82-05255 5A

ONTARIO
The Dissipation of Nonylphenol in Stream and Pond Water Under Simulated Field Conditions,
W82-05273 5B

Radiotracer Experiments on Phosphorus Uptake and Release by Limnetic Microzooplankton,
W82-05381 5B

River Basin Management in Ontario,
W82-05393 6E

Direct Snow-Water Equivalent Measurements by Air-Borne Gamma-Ray Spectrometry,
W82-05643 2C

OPEN-CHANNEL FLOW
Resistance of Beauharnois Canal in Winter,
W82-04998 2C

Nature of Wave Attenuation in Open Channel Flow,
W82-05003 2E

The Rotating Hydraulics of the Open-Channel Flow Between Two Basins,
W82-05083 8B

OPEN CHANNELS
Circular Wall Jets in Coflowing Streams,
W82-04999 5B

On Measuring Time-Averaged Velocities in Open Channel Flow,
W82-05462 2J

The Properties of the Kernels of the Volterra Series Describing Flow Deviations from a Steady State in an Open Channel,
W82-05525 2E

Flow Resistance in Wide Rectangular Channels,
W82-05798 8B

OPEN WELLS
Bottom-Entry Large-Diameter Wells,
W82-04919 8A

OPERATING POLICIES
Seasonal Risk-Based Reservoir Operating Rules,
W82-05299 4A

Modified Standard Operation Rules for Reservoirs,
W82-05658 4A

OPERATIONS RESEARCH
Operational Research Techniques in River Basin Management,
W82-05387 6A

OPTIMIZATION
Use of Mathematical Models to Generate Alternative Solutions to Water Resources Planning Problems,
W82-05072 6A

Integrated Management of Water Deficits and Floods in a Reservoir System,
W82-05325 4A

Modified Standard Operation Rules for Reservoirs,
W82-05658 4A

Multi-Decision Analysis for Large-Scale River-Basin Reservoir Systems,
W82-05659 2E

Algorithm for Optimal Activated Sludge Operation,
W82-05682 5D

An Application of Mathematical Programming to Water Resources Planning: An Economic View,
W82-05737 6A

Optimal Location and Management of Waste Disposal Facilities Affecting Ground Water Quality,
W82-05740 5G

OPTIMUM DEVELOPMENT PLANS
Multi-Decision Analysis for Large-Scale River-Basin Reservoir Systems,
W82-05659 2E

Optimal Salinity Control Program for the Upper Colorado River Basin,
W82-05893 5G

ORCHARDS
Irrigation Efficiency in Orchards,
W82-05768 3F

OREGON
Petroleum Refinery Wastewater Induction of the Hepatic Mixed-Function Oxidase System in Pacific Staghorn Sculpin,
W82-04895 5C

Infiltration Inflow Analysis: Finding the Source,
W82-05038 5B

Bedload and Size Distribution in Paved Gravel-Bed Streams,
W82-05795 2J

ORGANIC CARBON
Performance of Granular Activated Carbon for Total Organic Carbon Removal,
W82-05677 5F

ORGANIC CHEMICALS
Organic Contaminants in the Suspended Sediments of the Niagara River,
W82-05636 5B

ORGANIC COMPOUNDS
Analysis of Volatile Organic Compounds in Water, Waste Water and an Industrial Effluent,
W82-04815 5A

Volatilization Rates of Intermediate and Low Volatility Chemicals from Water,
W82-04817 5B

Occurrence and Determination of Organic Oxidants in Rivers and Wastewaters,
W82-04821 5A

Biodegradation of Hazardous Organic Pollutants,
W82-04910 5B

Comparison of Photochemical Behavior of Various Humic Substances in Water: I. Sunlight Induced Reactions of Aquatic Pollutants Photosensitized,
W82-04914 2K

Comparison of Photochemical Behavior of Various Humic Substances in Water: II. Photosensitized Oxygenations,
W82-04915 2K

The New Pollution--Groundwater Contamination,
W82-04938 5C

Behavior of Organic Priority Pollutants in the Terrestrial System: Di-n-butyl Phthalate Ester, Toluene, and 2,4 Dinitrophenol,
W82-04965 5B

GC/MS Analysis of XAD-2 Extracts of Superchlorinated Septage,
W82-05016 5A

Removal of Water Soluble Hazardous Materials Spills from Waterways by Activated Carbon,
W82-05060 5G

Problems of the Detection of Organic Trace Substances in Water (Zu Problemen des Nachweises Organischer Spurenstoffe im Wasser),
W82-05093 5A

Selective Passage of Hydrophilic Nitrogenous Organic Materials Through Macroreticular Resins,
W82-05150 5D

Removal of Refractory Organics from Water by Aeration. I. Methyl Chloroform,
W82-05174 5D

Microbial Removal of Hazardous Organic Compounds,
W82-05177 5D

The use of Activated Carbon in Water Treatment,
W82-05182 5F

Containment and Treatment of the Love Canal Landfill Leachate,
W82-05250 5D

The Dissipation of Nonylphenol in Stream and Pond Water Under Simulated Field Conditions,
W82-05273 5B

The Aquatic Toxicity of Organic Compounds to Embryo-Larval Stages of Fish and Amphibians,
W82-05283 5C

Industrial Wastewater Treatment Technology--Recent Developments,
W82-05348 5D

Determination of Mutagenic Potential and Organic Contaminants of Great Lakes Drinking Water,
W82-05398 5A

Use of Synthetic Adsorbents in Chemical Processes,
W82-05404 5D

Procedures for Analyzing Contaminants in Drinking Water,
W82-05438 5A

Organic Groups and Molecular Weight Distribution in Tertiary Effluents and Renovated Waters,

W82-05140 2K

Microbial Ecology of Pectin Decomposition in Anoxic Lake Sediments,
W82-05275 2H

Organic Composition of Aerobic, Anaerobic, and Compost-Stabilized Sludges,
W82-05854 5E

ORGANIC PESTICIDES
Selected Organic Pesticides, Behavior and Removal from Domestic Wastewater by Chemical and Physical Processes,
W82-05481 5D

A New Sensitive and Simple Spot Test for the Detection of Tertiary Amine Pollutants in Water,
W82-05483 5A

ORGANIC POLLUTION
Planktonic Infusoria as Indicators of the Extent of Organic Pollution in Azerbaidzhanian Reservoirs,
W82-05454 2H

ORGANOCHLORINE
Organochlorine Pollutant Analysis of Contaminated and Uncontaminated Lake Sediments by High Resolution Gas Chromatography,
W82-04828 5A

ORGANOPHOSPHORUS PESTICIDES
Organochlorine Residues in Suspended Solids Collected from the Mouths of Canadian Streams Flowing into the Great Lakes 1974-1977,
W82-05635 5B

OSMOSIS
Further Results on the Performace of Present-Day Osmotic Membranes in Various Osmotic Regions,
W82-05660 3A

OTTAWA RIVER
Comparison of Trihalomethane Levels and Other Water Quality Parameters for Three Treatment Plants on the Ottawa River,
W82-04810 5F

OWLS HEAD TREATMENT PLANT
Conversion of Aerator to Chlorine Contact Tank at the Owls Head Water Pollution Control Plant,
W82-05402 5D

OXIDATION
Occurrence and Determination of Organic Oxidants in Rivers and Wastewaters,
W82-04821 5A

Extended Dechlorination Studies with Granular Activated Carbon Filters,
W82-05257 5F

Re-Examining the Kinetics of the Biochemical Oxidation of Sewage,
W82-05409 5D

OXIDATION PONDS
Carbon Limitation of Biomass Production in High-Rate Oxidation Ponds,
W82-05373 5D

OXYGEN
Saving Energy by Catalytic Reduction of Oxygen in Feedwater,
W82-05183 5F

Criteria for Nitrification in Fixed Film Reactors,
W82-05352 5D

Influence of High Partial Pressure of Carbon Dioxide and/or Oxygen on Nitrification,
W82-05498 5D

OXYGEN DEMAND
Characterization of Industrial Wastes by Evaluating BOD, COD, and TOC,
W82-05255 5A

Chemical and Biochemical Oxygen Demand as Indicators of Biodegradable Substrate Concentration,
W82-05466 5D

A Comparison of the Carbonaceous Oxygen Demands of a Domestic and Industrial Sewage,
W82-05467 5D

OXYGEN ISOTOPES
The Relationship Between 018 and Deuterium in Water in Sand Columns Undergoing Evaporation,
W82-05759 2G

OXYGEN TRANSFER

W82-05839 2A

SMITH MOUNTAIN LAKE
Performance of a Large Advanced Waste Treatment Plant,
W82-05251 5D

SNOW
The Determination of Heavy Metals (Al, Mn, Fe, Ni, Cu, Zn, Cd, and Pb) in Urban Snow Using an Atomic Absorption Graphite Furnace,
W82-05397 5A

Spectral Reflectances of Freshwater Ice and Snow from 340 Through 1100 NM,
W82-05556 2C

Snow Contamination by Heavy Metals and Sulphur in Cracow Agglomeration (Southern Poland),
W82-05783 5B

SNOW WATER EQUIVALENT
Direct Snow-Water Equivalent Measurements by Air-Borne Gamma-Ray Spectrometry,
W82-05643 2C

SNOWMELT
Evaluation of Snowmelt Forecasting Methods,
W82-05552 4A

Erosion from Mountain Snowpack Melt,
W82-05664 2J

Effect of Ashfall on Snowmelt Rate at Paradise, Mount Rainier, Washington,
W82-05871 2C

SOCIAL IMPACT
Family Life Cycle Disruption in Rural Communities: The Case of the Lake Shelbyville Reservoir,
W82-04966 4C

An Assessment of Geothermal Development in the Imperial Valley of California; Volume 1 - Environment, Health and Socio-economics,
W82-05214 6G

SOIL CEMENT
Consider Soil-Cement for Erosion and Seepage Control,
W82-05039 8F

SOIL CHEMISTRY
Slash Burning Effects on Soil and Water Chemistry in Southeastern Alaska,
W82-05715 4C

Leaching Fractions and Salt Status of Two Irrigated Gypsum-Rich Soils in Southern Alberta,
W82-05762 2G

SOIL CONSERVATION
Erosivity Values for Individual Design Storms,
W82-05694 4D

SOIL CONTAMINATION
Enhanced Biodegradation of Pesticides in Soil to Alleviate Contaminated Runoff,
W82-04967 5G

SOIL DENSITY
An Approximate Method of Estimating Soil Water Diffusivity for Different Soil Bulk Densities,
W82-05073 2G

SOIL DYNAMICS
Dynamic Elastic and Absorbing Properties of Soils,
W82-05132 8D

SOIL EROSION
Movement of Diffuse Source Pollutants in Small Agricultural Watersheds of the Great Lakes Basin,
W82-04856 5B

The Influence of Water Salinity on Paludal Erosion Processes,
W82-04995 2J

Erodibility of Selected Soils and Estimates of Sediment Yields in the San Juan Basin, New Mexico,
W82-05223 2J

A Stochastic Model of Soil Erosion,
W82-05298 2J

Erosion Control Potential with Conservation Tillage in the Lake Erie Basin: Estimates Using the Universal Soil Loss Equation and the Land Resource Information System (LRIS),
W82-05661 4D

SOIL MANAGEMENT
Optimizing the Use of Water and Nitrogen Through Soil and Crop Management,
W82-05609 3F

SOIL MECHANICS
Large-Scale Experimental Investigations of Failure of an Embankment Slope under Dynamic Loads,
W82-04774 8D

SOIL MOISTURE
Use of Spectral Data to Estimate the Relationship between Soil Moisture Tensions and Their Corresponding Reflectances,
W82-04963 2G

SOIL MOISTURE METERS
Simplifying Neutron Moisture Meter Calibration,
W82-05173 7B

SOIL MOISTURE RETENTIION
A Field Method for Measuring Short-Circuiting in Clay Soils,
W82-05626 2G

SOIL PHYSICAL PROPERTIES
Calculation of Large Unlined Canals,
W82-05131 8B

SOIL POROSITY
Design of the Composition of Transition Layers of Asphaltic Concrete Membranes in Earth Dams,
W82-05113 8A

Changes to a Soil on Irrigation with a Sanitary Landfill Leachate,
W82-05619 5E

SOIL STABILITY
$12.6 M Repairs Bill for Ruahihi Canal.
W82-05880 8D

SOIL TEMPERATURE
Calculation of the Temperature Regime of Hydraulic Fill Dams During Their Construction,
W82-04760 8D

SOIL TYPES
The Effect of Raindrop Impact on the Dynamics of Soil Surface Crusting and Water Movement in the Profile,
W82-04868 2G

Soil Water Intake Rates and Surface Irrigation System Characteristics by Soil Series in Southeastern Idaho,
W82-05539 3F

A Field Method for Measuring Short-Circuiting in Clay Soils,
W82-05626 2G

SOIL WATER
Use of Spectral Data to Estimate the Relationship between Soil Moisture Tensions and Their Corresponding Reflectances,
W82-04963 2G

An Approximate Method of Estimating Soil Water Diffusivity for Different Soil Bulk Densities,
W82-05073 2G

Optimization Principle for Air and Water Movement,
W82-05172 2G

Flexcrop: A Dryland Cropping Systems Model,
W82-05208 3F

Reduced Runoff and Nonpoint Source Pollution Through Increased Infiltration,
W82-05300 2G

Soil Water Intake Rates and Surface Irrigation System Characteristics by Soil Series in Southeastern Idaho,
W82-05539 3F

On Determining Volumetric Soil Moisture Variations in Peat by the Gravimetric Method,
W82-05616 2G

Soil Water Availability,
W82-05623 2G

A Field Method for Measuring Short-Circuiting in Clay Soils,
W82-05626 2G

SOIL-WATER-PLANT RELATIONSHIPS
Evaluation of the Effect of Linearization of the Magnus Equation on the Accuracy of Calculating Evaporation from the Surface of Moist Soil and Transpiration,
W82-05031 2D

Soil Water Availability,
W82-05623 2G

Deep Drainage and Water Use of Forests and Pastures Grown on Deep Sands in a Mediterranean Environment,
W82-05629 4B

SOLAR RADIATION
Photolysis of Polycyclic Aromatic Hydrocarbons in Water,
W82-04835 5B

SOLID WASTES
Reliability of Analytical Methods for Anaerobic Municipal Solid Waste Samples,
W82-04789 5A

SOLUBILITY
Oil Slick Mechanics,
W82-05064 5G

The Effect of Pressure on the Solubility of Minerals in Water and Seawater,
W82-05135 1B

Fluorapatite and Fluorite Solubility Controls on Geothermal Waters in Yellowstone National Park,
W82-05449 2K

The Effect of Sulfate on Aluminum Concentrations in Natural Waters: Some Stability Relations in the System Al2O3-SO3-H2O at 298 K,
W82-05581 2K

SOLUTE TRANSPORT
Application of an Approximate Analytic Method of Computing Solute Profiles with Dispersion in Soils,
W82-04876 5B

A Contribution to Simplified Models of Field Solute Transport,
W82-04877 5B

Numerical Simulation of the Transport and Speciation of Nonconservative Chemical Reactants in Rivers,
W82-05079 5B

Optimal Dynamic Management of Groundwater Pollutant Sources,
W82-05345 5G

Hydrodynamic Dispersion During Absorption in a Fine Sand 1. The Constant Concentration Case,
W82-05347 5B

Role of Sediment in Non-Point Source Salt Loading within the Upper Colorado River Basin,
